
celloracle

Release 0.6.9

Samantha Morris Lab

Jun 10, 2021

CONTENTS

1	Contents	3
1.1	Installation	3
1.2	Tutorial	7
1.3	Google Colaboratoly	110
1.4	API	110
1.5	Changelog	133
1.6	License	134
1.7	Authors and citations	136
2	Indices and tables	139
	Python Module Index	141
	Index	143

CellOracle is a python library for the analysis of Gene Regulatory Network with single cell data.

Source code is available at [celloracle GitHub repository](#)

For more information, please read our bioarxiv preprint: [CellOracle: Dissecting cell identity via network inference and in silico gene perturbation](#)

Note:

Documentation is also available as a pdf file.

[pdf documentation](#)

Warning: CellOracle is still under development. It is beta version and functions in this package may change in the future release.

CONTENTS

1.1 Installation

`celloracle` uses several python libraries and R library. Please follow this guide below to install the dependent software of `celloracle`.

1.1.1 Docker image

- Not available now. Coming soon.

1.1.2 System Requirements

- Operating system: macOS or linux are highly recommended. `celloracle` was developed and tested in Linux and macOS.
- We found that the `celloracle` calculation may be EXTREMELY SLOW under an environment of Windows Subsystem for Linux (WSL). We do not recommend using WSL.
- While you can install `celloracle` in Windows OS, please do so at your own risk and responsibility. We DO NOT provide any support for the use in the Windows OS.
- Memory: 8 G byte or more. Memory usage also depends on your scRNA-seq data. Especially in silico perturbation requires large amount of memory.
- CPU: Core i5 or better processor. GRN inference supports multicore calculation. Higher number of CPU cores enables faster calculation.

1.1.3 Python Requirements

- `celloracle` was developed with python 3.6. We do not support python 2.7x or python <=3.5.
- Please install all dependent libraries before installing `celloracle` according to the instructions below.
- `celloracle` is still beta version and it is not available through PyPI or anaconda distribution yet. Please install `celloracle` from GitHub repository according to the instruction below.

0. (Optional) Make a new environment

This step is optional. Please make a new python environment for celloracle and install dependent libraries in it if you get some software conflicts.

```
conda create -n celloracle_env python=3.6
conda activate celloracle_env
```

1. Add conda channels

Installation of some libraries requires non-default anaconda channels. Please add the channels below. Instead, you can explicitly enter the channel when you install a library.

```
conda config --add channels defaults
conda config --add channels bioconda
conda config --add channels conda-forge
```

2. Install velocyto

Please install velocyto with the following commands or the author's instruction .

```
conda install numpy scipy cython numba matplotlib scikit-learn h5py>=3.1.0 click_
↪pysam llvm louvain
```

Then

```
pip install velocyto
```

It was reported that some compile errors might occur during the installation of velocyto on MacOS. Various errors were reported and you need to find the best solution depending on your error. You may find the solution with these links below.

- Solution 1: Install Xcode. Please try this first.
- Solution 2: Install `macOS_SDK_headers`. This solution is needed in addition to Solution-1 if your OS is MacOS Mojave.
- Solution 3. This is the solution reported by a CellOracle user. Thank you very much!
- Other solutions on [Velocyto github issue page](#)

3. Install scanpy

Please install scanpy with the following commands or the author's instruction .

```
conda install scanpy
```

4. Install other python libraries

Please install other python libraries below with the following commands.

```
conda install goatools pyarrow tqdm joblib jupyter gimmermotifs==0.14.4 genomepy==0.8.4
```

5. install celloracle from github

```
pip install git+https://github.com/morris-lab/CellOracle.git
```

1.1.4 R requirements

celloracle use R libraries for the network analysis and scATAC-seq analysis. Please install [R](#) (≥ 3.5) and R libraries below according to the author's instruction.

Seurat

Please install Seurat with the following r-script or [the author's instruction](#). celloracle is compatible with both Seurat V2 and V3. If you use only scanpy for the scRNA-seq preprocessing and do not use Seurat , you can skip installation of Seurat.

In R console,

```
install.packages('Seurat')
```

Cicero

Please install Cicero and Monocle3 with the following r-script or [the author's instruction](#). If you do not have scATAC-seq data and plan to use celloracle's base GRN, you do not need to install Cicero.

In R console,

```
if (!requireNamespace("BiocManager", quietly = TRUE))
  install.packages("BiocManager")
BiocManager::install(c("Gviz", "GenomicRanges", "rtracklayer"))

install.packages("devtools")
devtools::install_github("cole-trapnell-lab/cicero-release", ref = "monocle3")
```

igraph

Please install igraph with the following r-script or [the author's instruction](#).

In R console,

```
install.packages("igraph")
```

linkcomm

Please install `linkcomm` with the following r-script or the author's instruction .

In R console,

```
install.packages("linkcomm")
```

rnetcarto

Please install `rnetcarto` with the following r-script or the author's instruction .

In R console,

```
install.packages("rnetcarto")
```

Check installation

These R libraries above are necessary for the network analysis in celloracle. You can check installation using celloracle's function.

In python console,

```
import celloracle as co
co.network_analysis.test_R_libraries_installation()
```

Please make sure that all R libraries are installed. The following message will be shown when all R libraries are appropriately installed.

R path: /usr/lib/R/bin/R

```
checking R library installation: igraph -> OK
checking R library installation: linkcomm -> OK
checking R library installation: rnetcarto -> OK
```

The first line above is your R path. If you want to use another R program that was installed at the different place, you can set new R path with the following command.

```
co.network_analysis.set_R_path("ENTER YOUR R PATH HERE")
```

If you changed R path settings, please check installation again to make sure everything works.

```
co.network_analysis.test_R_libraries_installation()
```

1.2 Tutorial

The analysis proceeds through multiple steps. Please run the notebooks sequentially. If you do not have ATAC-seq data and want to use the default TF binding information, you can skip the first and second step and start from the third step.

Please refer to the `celloracle` paper for scientific premise and the detail of the algorithm of celloracle.

The jupyter notebook files and data used in this tutorial are available [here](#).

1.2.1 ATAC-seq data preprocessing

In this step, we process scATAC-seq data (or bulk ATAC-seq data) to obtain the accessible promoter/enhancer DNA sequence. We can get the active proximal promoter/enhancer genome sequences by picking up the ATAC-seq peaks that exist around the transcription starting site (TSS). Distal cis-regulatory elements can be picked up using `Cicero`. Cicero analyzes scATAC-seq data to calculate a co-accessible score between peaks. We can identify cis-regulatory elements using Cicero's co-access score and TSS information.

If you have bulk ATAC-seq data instead of scATAC-data, we'll get only the proximal promoter/enhancer genome sequences.

A. Extract TF binding information from scATAC-seq data

If you have scATAC-seq data, you can get information on the distal cis-regulatory elements. This step uses Cicero and does not use celloracle. You need to get co-accessibility table in this analysis. Although we provide an example notebook here, you can analyze your data with Cicero in a different way if you are familiar with Cicero. If you have a question about Cicero, please read the documentation of `Cicero` for the detailed usage.

scATAC-seq analysis with Cicero and Monocle3

The jupyter notebook files and data used in this tutorial are available [here](#).

R notebook

This is an example R script for Cicero analysis. In this R notebook, we'll use Cicero and Monocle3.

Please make sure that you installed these packages in advance.

You can download notebook file and additional data files from celloracle github page. https://github.com/morris-lab/CellOracle/tree/master/docs/notebooks/01_ATAC-seq_data_processing/option1_scATAC-seq_data_analysis_with_cicero

Another tutorial notebook that uses Monocle2 is also available in the celloracle github page above.

0. Import library

```
[2]: library(cicero)
library(monocle3)
```

1. Prepare data

In this tutorial we'll use acATAC-seq data from the 10x genomics database. You do not need to download these data if you analyze your own scATAC-seq data.

```
[4]: # Create folder to store data
dir.create("data")

# Download demo dataset from 10x genomics
system("wget -O data/matrix.tar.gz http://cf.10xgenomics.com/samples/cell-atac/1.1.0/
→atac_v1_E18_brain_fresh_5k/atac_v1_E18_brain_fresh_5k_filtered_peak_bc_matrix.tar.gz
→")

# Unzip data
system("tar -xvf data/matrix.tar.gz -C data")
```

```
[6]: # You can substitute the data path below with the data path of your scATAC data.
data_folder <- "data/filtered_peak_bc_matrix"

# Create a folder to save results
output_folder <- "cicero_output"
dir.create(output_folder)
```

2. Load data and make Cell Data Set (CDS) object

2.1. Process data to make CDS object

```
[7]: # read in matrix data using the Matrix package
indata <- Matrix:::readMM(paste0(data_folder, "/matrix.mtx"))
# binarize the matrix
indata@x[indata@x > 0] <- 1

# format cell info
cellinfo <- read.table(paste0(data_folder, "/barcodes.tsv"))
row.names(cellinfo) <- cellinfo$V1
names(cellinfo) <- "cells"

# format peak info
peakinfo <- read.table(paste0(data_folder, "/peaks.bed"))
names(peakinfo) <- c("chr", "bp1", "bp2")
peakinfo$site_name <- paste(peakinfo$chr, peakinfo$bp1, peakinfo$bp2, sep="_")
row.names(peakinfo) <- peakinfo$site_name

row.names(indata) <- row.names(peakinfo)
colnames(indata) <- row.names(cellinfo)

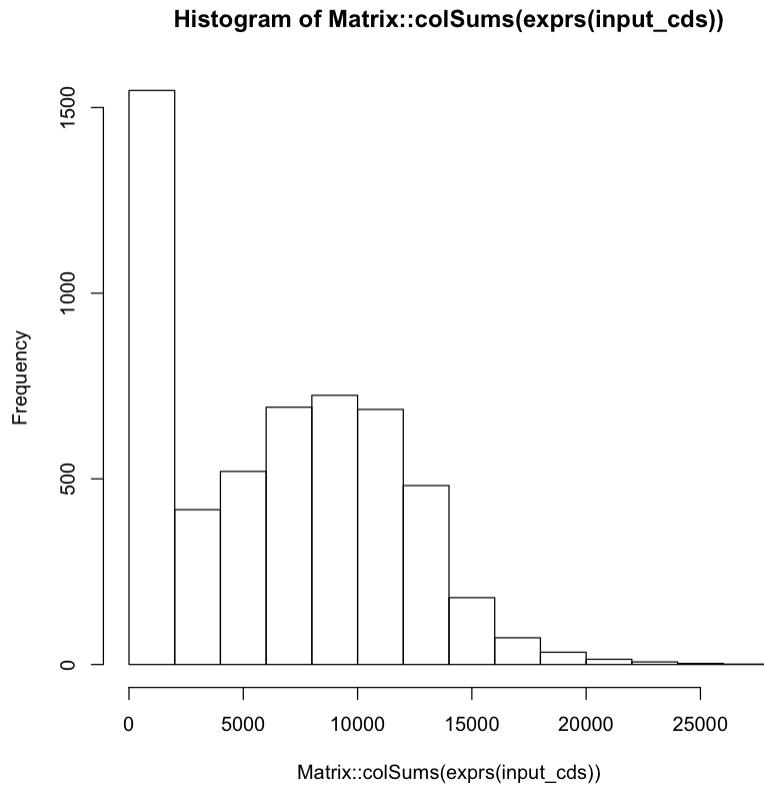

# make CDS
input_cds <- suppressWarnings(new_cell_data_set(indata,
cell_metadata = cellinfo,
gene_metadata = peakinfo))

input_cds <- monocle3::detect_genes(input_cds)

#Ensure there are no peaks included with zero reads
input_cds <- input_cds[Matrix:::rowSums(exprs(input_cds)) != 0,]
```

3. Quality check and Filtering

```
[8]: # Visualize peak_count_per_cell
hist(Matrix::colSums(exprs(input_cds)))
```

```
[9]: # filter cells by peak_count
# PLEASE SET APPROPRIATE THRESHOLD VALUES according to your data
max_count <- 15000
min_count <- 2000
input_cds <- input_cds[, Matrix::colSums(exprs(input_cds)) >= min_count]
input_cds <- input_cds[, Matrix::colSums(exprs(input_cds)) <= max_count]
```

4. Process cicero-CDS object

```
[ ]: # Data preprocessing
set.seed(2017)

input_cds <- detect_genes(input_cds)
input_cds <- estimate_size_factors(input_cds)
input_cds <- preprocess_cds(input_cds, method = "LSI")

# Dimensional reduction with umap
input_cds <- reduce_dimension(input_cds, reduction_method = 'UMAP',
                                preprocess_method = "LSI")
```

(continues on next page)

(continued from previous page)

```
umap_coords <- reducedDims(input_cds)$UMAP

cicero_cds <- make_cicero_cds(input_cds, reduced_coordinates = umap_coords)

# Save cds object if you want
saveRDS(cicero_cds, paste0(output_folder, "/cicero_cds.Rds"))
```

5. Load reference genome information

To run cicero, we need to get a genome coordinates files, which contains the lengths of each chromosomes. You can read mm10 genome information with the following command. The text file, mm10_chromosome_length.txt is included in the celloracle notebook folder.

https://github.com/morris-lab/CellOracle/tree/master/docs/notebooks/01_ATAC-seq_data_processing/option1_scATAC-seq_data_analysis_with_cicero

If your scATAC-seq data use different reference genome, you need to get a genome coordinates files for your reference genome. Please see the Cicero documentation for more information.

https://cole-trapnell-lab.github.io/cicero-release/docs_m3/#installing-cicero

```
[ ]: # !!Please make sure that the reference genome information below match the reference_
  ↪genome of your scATAC-seq data.

# If your scATAC-seq uses mm10 reference genome, you can read chromosome length file_
  ↪with the following command.
chromosome_length <- read.table("./mm10_chromosome_length.txt")

# For mm9 genome, you can use the following command.
#data("mouse.mm9.genome")
#chromosome_length <- mouse.mm9.genome

# For hg19 genome, you can use the following command.
#data("human.hg19.genome")
#chromosome_length <- mhuman.hg19.genome
```

6. Run Cicero

```
[11]: # run the main function
conns <- run_cicero(cicero_cds, chromosome_length) # Takes a few minutes to run

# save results
saveRDS(conns, paste0(output_folder, "/cicero_connections.Rds"))

# check results
head(conns)

[1] "Starting Cicero"
[1] "Calculating distance_parameter value"
```

(continues on next page)

(continued from previous page)

```
[1] "Running models"
[1] "Assembling connections"
[1] "Done"
```

	Peak1 <fct>	Peak2 <fct>	coaccess <dbl>
A data.frame: 6 × 3	2 chr1_3094484_3095479	chr1_3113499_3113979	-0.316289004
	3 chr1_3094484_3095479	chr1_3119478_3121690	-0.419240532
	4 chr1_3094484_3095479	chr1_3399730_3400368	-0.050867246
	5 chr1_3113499_3113979	chr1_3094484_3095479	-0.316289004
	7 chr1_3113499_3113979	chr1_3119478_3121690	0.370342744
	8 chr1_3113499_3113979	chr1_3399730_3400368	-0.009276026

6. Save results for the next step

```
[ ]: all_peaks <- row.names(exprs(input_cds))
write.csv(x = all_peaks, file = paste0(output_folder, "/all_peaks.csv"))
write.csv(x = conns, file = paste0(output_folder, "/cicero_connections.csv"))
```

TSS annotation

The jupyter notebook files and data used in this tutorial are available [here](#).

Python notebook

In this notebook, we process the results of cicero analysis to get active promoter/enhancer DNA peaks. First, we pick up peaks around the transcription starting site (TSS). Second, we merge cicero data with the peaks around TSS. Then we remove peaks that have a weak connection to TSS peak so that the final product includes TSS peaks and peaks that have a strong connection with the TSS peaks. We use this information as an active promoter/enhancer elements.

0. Import libraries

```
[1]: import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
%matplotlib inline

import seaborn as sns

import os, sys, shutil, importlib, glob
from tqdm.notebook import tqdm

from celloracle import motif_analysis as ma
```

```
[2]: %config InlineBackend.figure_format = 'retina'

plt.rcParams['figure.figsize'] = [6, 4.5]
plt.rcParams["savefig.dpi"] = 300
```

1. Load data made with cicero

```
[3]: # Load all peaks
peaks = pd.read_csv("cicero_output/all_peaks.csv", index_col=0)
peaks = peaks.x.values
peaks

[3]: array(['chr1_3094484_3095479', 'chr1_3113499_3113979',
       'chr1_3119478_3121690', ..., 'chrY_90804622_90805450',
       'chrY_90808626_90809117', 'chrY_90810560_90811167'], dtype=object)

[4]: # Load cicero results
cicero_connections = pd.read_csv("cicero_output/cicero_connections.csv", index_col=0)
cicero_connections.head()

/home/k/anaconda3/envs/test/lib/python3.6/site-packages/numpy/lib/arraysetops.py:568:
  ↪FutureWarning: elementwise comparison failed; returning scalar instead, but in the
  ↪future will perform elementwise comparison
    mask |= (ar1 == a)

[4]:          Peak1            Peak2   coaccess
2  chr1_3094484_3095479  chr1_3113499_3113979 -0.316289
3  chr1_3094484_3095479  chr1_3119478_3121690 -0.419241
4  chr1_3094484_3095479  chr1_3399730_3400368 -0.050867
5  chr1_3113499_3113979  chr1_3094484_3095479 -0.316289
7  chr1_3113499_3113979  chr1_3119478_3121690  0.370343
```

2. Make TSS annotation

IMPORTANT: Please make sure that you are setting correct reference genome.

If your scATAC-seq data was generated with mm10 reference genome, you can set ref_genome="mm10". If you used hg19 human reference genome, please set ref_genome=="hg19"

Currently we support refgenomes below. {"Human": ["hg38", "hg19"], "Mouse": ["mm10", "mm9"], "S.cerevisiae": ["sacCer2", "sacCer3"]}

If your reference genome is not in the list, please send a request through github issue page.

```
[5]: tss_annotated = ma.get_tss_info(peak_str_list=peaks, ref_genome= ) ####! Set reference
  ↪genome here

# Check results
tss_annotated.tail()

que bed peaks: 72402
tss peaks in que: 16987

[5]:      chr      start        end gene_short_name strand
16982  chr1    55130650  55132118        Mob4        +
16983  chr6    94499875  94500767        S1c25a26      +
16984  chr19   45659222  45660823        Fbxw4        -
16985  chr12   100898848 100899597        Gpr68        -
16986  chr4    129491262 129492047        Fam229a      -
```

3. Integrate TSS info and cicero connections

The output file after the integration process has three columns; “peak_id”, “gene_short_name”, and “coaccess”. “peak_id” is either the TSS peak or the peaks that have a connection with the TSS peak. “gene_short_name” is the gene name that associated with the TSS site. “coaccess” is the co-access score between a peak and TSS peak. Note, the TSS peak is indicated by a score of 1.

```
[8]: integrated = ma.integrate_tss_peak_with_cicero(tss_peak=tss_annotated,
                                                    cicero_connections=cicero_connections)
print(integrated.shape)
integrated.head()
(263279, 3)

[8]:          peak_id gene_short_name  coaccess
0  chr10_100015291_100017830      Kitl  1.000000
1  chr10_100018677_100020384      Kitl  0.086299
2  chr10_100050858_100051762      Kitl  0.034558
3  chr10_100052829_100053395      Kitl  0.167188
4  chr10_100128086_100128882     Tmtc3  0.022341
```

4. Filter peaks

Remove peaks that have weak coaccess score.

```
[9]: peak = integrated[integrated.coaccess >= 0.8]
peak = peak[["peak_id", "gene_short_name"]].reset_index(drop=True)

[10]: print(peak.shape)
peak.head()
(15680, 2)

[10]:          peak_id gene_short_name
0  chr10_100015291_100017830      Kitl
1  chr10_100486534_100488209     Tmtc3
2  chr10_100588641_100589556  4930430F08Rik
3  chr10_100741247_100742505      Gm35722
4  chr10_101681379_101682124     Mgat4c
```

5. Save data

Save the promoter/enhancer peak.

```
[11]: peak.to_parquet("peak_file.parquet")
```

-> go to next notebook

B. Extract TF binding information from bulk ATAC-seq data or Chip-seq data

Bulk DNA-seq data can be used to get the accessible promoter/enhancer sequences.

The jupyter notebook files and data used in this tutorial are available [here](#).

Python notebook

0. Import libraries

```
[1]: import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
%matplotlib inline

import seaborn as sns

import os, sys, shutil, importlib, glob
from tqdm import tqdm_notebook as tqdm

%config InlineBackend.figure_format = 'retina'

plt.rcParams['figure.figsize'] = [6, 4.5]
plt.rcParams["savefig.dpi"] = 300
```

```
[2]: # Import celloracle function
from celloracle import motif_analysis as ma
```

1. Load bed file

Import ATAC-seq bed file. This script can also be used with DNase-seq or Chip-seq data.

```
[3]: file_path_of_bed_file = "data/all_peaks.bed"

[4]: # Load bed_file
bed = ma.read_bed(file_path_of_bed_file)
print(bed.shape)
bed.head()
(436206, 4)

[4]:   chrom      start        end      seqname
0  chr1  3002478  3002968  chr1_3002478_3002968

3. Save data

```
[10]: tss_annotated.to_parquet("peak_file.parquet")
```

-> go to next notebook

1.2.2 Transcription factor binding motif scan

We identified accessible Promoter/enhancer DNA regions using ATAC-seq data. Next, we will obtain a list of TFs for each target gene by scanning the regulatory genomic sequences for TF-binding motifs. In the later GRN inference process, this list will be used to define potential regulatory connections.

The jupyter notebook files and data used in this tutorial are available [here](#).

Scan DNA sequences searching for TF binding motifs

Python notebook

0. Import libraries

```
[1]: import pandas as pd
import numpy as np
import matplotlib.pyplot as plt

import seaborn as sns

import os, sys, shutil, importlib, glob
from tqdm.notebook import tqdm
```

```
[2]: from celloracle import motif_analysis as ma
from celloracle.utility import save_as_pickled_object
```

```
[3]: %config InlineBackend.figure_format = 'retina'
%matplotlib inline

plt.rcParams['figure.figsize'] = (15, 7)
plt.rcParams["savefig.dpi"] = 600
```

1. Reference genome data preparation

1.1. Check reference genome installation

Celloracle uses genomepy to get DNA sequence data. Before starting celloracle analysis, we need to make sure that the reference genome is correctly installed in your computational environment. If not, please install reference genome.

```
[4]: # PLEASE make sure that you are setting correct ref genome.
ref_genome = "mm10"

genome_installation = ma.is_genome_installed(ref_genome=ref_genome)
print(ref_genome, "installation:", genome_installation)

mm10 installation: True
```

1.2. Install reference genome (if refgenome is not installed)

```
[5]: if not genome_installation:
    import genomepy
    genomepy.install_genome(ref_genome, "UCSC")
else:
    print(ref_genome, "is installed.")

mm10 is installed.
```

2. Load data

2.1. Load processed peak data

```
[6]: # Load annotated peak data.
peaks = pd.read_parquet("../01_ATAC-seq_data_processing/option1_scATAC-seq_data_"
                       "analysis_with_cicero/peak_file.parquet")
peaks.head()

[6]:
          peak_id gene_short_name
0  chr10_100015291_100017830        Kitl
1  chr10_100486534_100488209        Tmtc3
2  chr10_100588641_100589556  4930430F08Rik
3  chr10_100741247_100742505        Gm35722
4  chr10_101681379_101682124        Mgat4c
```

2.1. Check data

```
[7]: # Define function for quality check
def decompose_chrstr(peak_str):
    """
    Args:
        peak_str (str): peak_str. e.g. 'chr1_3094484_3095479'

    Returns:
        tuple: chromosome name, start position, end position
    """
    *chr_, start, end = peak_str.split("_")
    chr_ = "_".join(chr_)
    return chr_, start, end

from genomepy import Genome

def check_peak_fomat(peaks_df, ref_genome):
    """
    Check peak fomat.
    (1) Check chromosome name.
    (2) Check peak size (length) and remove sort DNAs (<5bp)

    """
    df = peaks_df.copy()

    n_peaks_before = df.shape[0]

    # Decompose peaks and make df
    decomposed = [decompose_chrstr(peak_str) for peak_str in df["peak_id"]]
    df_decomposed = pd.DataFrame(np.array(decomposed))
    df_decomposed.columns = ["chr", "start", "end"]
    df_decomposed["start"] = df_decomposed["start"].astype(np.int)
    df_decomposed["end"] = df_decomposed["end"].astype(np.int)

    # Load genome data
    genome_data = Genome(ref_genome)
```

(continues on next page)

(continued from previous page)

```

all_chr_list = list(genome_data.keys())

# DNA length check
lengths = np.abs(df_decomposed["end"] - df_decomposed["start"])

# Filter peaks with invalid chromosome name
n_threshold = 5
df = df[(lengths >= n_threshold) & df_decomposed.chr.isin(all_chr_list)]

# DNA length check
lengths = np.abs(df_decomposed["end"] - df_decomposed["start"])

# Data counting
n_invalid_length = len(lengths[lengths < n_threshold])
n_peaks_invalid_chr = n_peaks_before - df_decomposed.chr.isin(all_chr_list).sum()
n_peaks_after = df.shape[0]

#
print("Peaks before filtering: ", n_peaks_before)
print("Peaks with invalid chr_name: ", n_peaks_invalid_chr)
print("Peaks with invalid length: ", n_invalid_length)
print("Peaks after filtering: ", n_peaks_after)

return df

```

[8]:

```

peaks = check_peak_fomat(peaks, ref_genome)

Peaks before filtering: 15680
Peaks with invalid chr_name: 0
Peaks with invalid length: 0
Peaks after filtering: 15680

```

2.2. [Optional step] Load motifs

You can select TF binding motif data for Celloracle motif analysis. If you have no preference and just want to use a default motif, you can skip this step. If you want to use a non-default motif dataset, please prepare motif data as a list of motif class in gimmemotifs. We have several option for loading motif database as below.

2.2.1. [Optional step] Load motif data from gimmemotifs dataset

Many motif databases are included with GimmeMotifs. <https://gimmemotifs.readthedocs.io/en/master/overview.html>
You can load them as follows.

[9]:

```

# First, we need to pick up motifs for your dataset. We can get a list.

# Get folder path that stores motif data.
import os, glob
from gimmemotifs.motif import MotifConfig
config = MotifConfig()
motif_dir = config.get_motif_dir()

```

(continues on next page)

(continued from previous page)

```
# Get list for motif data name
motifs_data_name = [i for i in os.listdir(motif_dir) if i.endswith(".pfm")]
motifs_data_name.sort()
motifs_data_name
```

[9]:

```
['CIS-BP.pfm',
 'ENCODE.pfm',
 'HOCOMOCov10_HUMAN.pfm',
 'HOCOMOCov10_MOUSE.pfm',
 'HOCOMOCov11_HUMAN.pfm',
 'HOCOMOCov11_MOUSE.pfm',
 'HOMER.pfm',
 'IMAGE.pfm',

```

2.2.2 [Optional step] Load motif data from celloracle motif dataset

Celloracle also provides many motif dataset that was generated from CisBP. <http://cisbp.ccbr.utoronto.ca/>

These motifs were organized by each species. Please select motifs for your species.

If you have a request for motifs for a new species, you can ask us to add new motifs through github issue page.

```
[11]: # Check available motifs
ma.MOTIFS_LIST
```

```

3. Instantiate TFinfo object and search for TF binding motifs

The motif analysis module has a custom class; TFinfo. The TFinfo object converts a peak data into a DNA sequences and scans the DNA sequences searching for TF binding motifs. Then, the results of motif scan will be filtered and converted into either a python dictionary or a depending on your preference. This TF information is necessary for GRN inference.

3.1. Instantiate TFinfo object

```
[16]: # Instantiate TFinfo object
tfi = ma.TFinfo(peak_data_frame=peaks, # peak info calculated from ATAC-seq data
                 ref_genome=ref_genome)
```

3.2. Motif scan

!!You can set TF binding motif information as an argument:

```
tfi.scan(motifs=motifs)
```

If you don't set motifs or set None, default motifs will be loaded automatically.

- For mouse and human, “gimme.vertebrate.v5.0.” will be used as a default motifs.
- For another species, a species specific TF binding motif data extracted from CisBP ver2.0 will be used.

```
[ ]: %%time
# Scan motifs. !!CAUTION!! This step may take several hours if you have many peaks!
tfi.scan(fpr=0.02,
          motifs=None, # If you enter None, default motifs will be loaded.
          verbose=True)

# Save tfinfo object
tfi.to_hdf5(file_path="test1.celloracle.tfinfo")
```

```
[16]: # Check motif scan results
tfi.scanned_df.head()
```

	seqname	motif_id	factors_direct	\
0	chr10_100015291_100017830	GM.5.0.Homeodomain.0001	TGIF1	
1	chr10_100015291_100017830	GM.5.0.Mixed.0001		
2	chr10_100015291_100017830	GM.5.0.Mixed.0001		
3	chr10_100015291_100017830	GM.5.0.Mixed.0001		
4	chr10_100015291_100017830	GM.5.0.Nuclear_receptor.0002	NR2C2	

	factors_indirect	score	pos	strand
0	ENSG00000234254, TGIF1	10.311002	1003	1
1	SRF, EGR1	7.925873	481	1
2	SRF, EGR1	7.321375	911	-1
3	SRF, EGR1	7.276585	811	-1
4	NR2C2, Nr2c2	9.067331	449	-1

We have the score for each sequence and motif_id pair. In the next step we will filter the motifs with low score.

4. Filtering motifs

```
[15]: # Reset filtering
tfi.reset_filtering()

# Do filtering
tfi.filter_motifs_by_score(threshold=10.5)

# Do post filtering process. Convert results into several file format.
tfi.make_TFinfo_dataframe_and_dictionary(verbose=True)

peaks were filtered: 12952283 -> 2288874
1. converting scanned results into one-hot encoded dataframe.

HBox(children=(FloatProgress(value=0.0, max=14142.0), HTML(value='')))

2. converting results into dictionaries.
converting scan results into dictionaries...

HBox(children=(FloatProgress(value=0.0, max=15006.0), HTML(value='')))

HBox(children=(FloatProgress(value=0.0, max=1090.0), HTML(value='')))
```

5. Get Final results

5.1. Get results as a dictionary

```
[23]: td = tfi.to_dictionary(dictionary_type="targetgene2TFs")
```

5.2. Get results as a dataframe

```
[17]: df = tfi.to_dataframe()
df.head()

[5 rows x 1092 columns]

6. Save TFinfo as dictionary or dataframe

We'll use this information when making the GRNs. Save the results.

```
[19]: folder = "TFinfo_outputs"
os.makedirs(folder, exist_ok=True)

# save TFinfo as a dictionary
td = tfi.to_dictionary(dictionary_type="targetgene2TFs")
save_as_pickled_object(td, os.path.join(folder, "TFinfo_targetgene2TFs.pickled"))

# save TFinfo as a dataframe
df = tfi.to_dataframe()
df.to_parquet(os.path.join(folder, "TFinfo_dataframe.parquet"))
```

[Optional step 1] How to use different motif data

Celloracle motif analysis pipeline provides several default motifs. If you don't enter motif data, celloracle automatically load default motifs for your species. In that case, you don't need to make TF binding motifs. But also, you can pick up TF binding motifs by yourself. Here, we introduce how to find and load motifs for celloracle motif analysis. Some codes for custom motif were based on the suggestion in [this post](#). from KyleFerchen. Thank you Kyle!

0. Overview: How to use a different motifs for celloracle motif scan.

In this notebook, we introduce how to prepare motif dataset for celloracle motif analysis. Celloracle uses list of motif object in `gimmemotifs` package. See `gimmemotifs` documentation for more details. (<https://gimmemotifs.readthedocs.io/en/master/api.html#>)

1 Import motifs from `gimmemotifs` dataset.

`Gimmemotifs` provides many motif dataset that was generated from public motif database including CisDB, ENCODE, HOMER, and JASPAR. <https://gimmemotifs.readthedocs.io/en/master/overview.html>

1.1 gimme.vertebrate.v5.0.

By default GimmeMotifs uses a non-redundant, clustered database of known vertebrate motifs. These motifs come from CIS-BP (<http://cisbp.ccbr.utoronto.ca/>) and other sources. This motif dataset can be easily loaded with the following command.

If your dataset is Mouse or Human, this one will be a good default choice.

```
[1]: # Compare with default motifs in gimmemotifs
from gimmemotifs.motif import default_motifs
motifs = default_motifs()

# Check first 10 motifs
motifs[:10]
```

```
[1]: [GM.5.0.Sox.0001_AACAAT,
GM.5.0.Homeodomain.0001_AGCTGTCAAnA,
GM.5.0.Mixed.0001_snnGGssGGs,
GM.5.0.Nuclear_receptor.0001_TAwstrGGTCAsTrGGTCA,
GM.5.0.Mixed.0002_GCTAATTA,
GM.5.0.Nuclear_receptor.0002_wnyrCTTCCGGGkC,
GM.5.0.bHLH.0001_ACGTG,
GM.5.0.Myb_SANT.0001_rrCCGTTAACnGyy,
GM.5.0.C2H2_ZF.0001_GCGkGGGCGG,
GM.5.0.GATA.0001_TTATCTsnnnnnnnCA]
```

1.2 Motifs that are provided with gimmemotifs package

Many other motif databases come included with GimmeMotifs. You can load them as follows.

```
[2]: # Get folder path that stores motif data.
import os, glob
from gimmemotifs.motif import MotifConfig
config = MotifConfig()
motif_dir = config.get_motif_dir()

# Get motif data names
motifs_data_name = [i for i in os.listdir(motif_dir) if i.endswith(".pfm")]
motifs_data_name.sort()
motifs_data_name
```

```

```

3. Import motifs from custom motif dataset.

If you want to use another motif data source, you need to make a list of motif class in `gimmemotifs`. The easiest way to make such object is to use “`read_motifs`” function in `gimmemotifs`.

This function can load motif data text file. You need to prepare two files, `XXX.motif2factors.txt` and `XXX.pfm`.

3.1 XXX.motif2factors.txt

The text file, `XXX.motif2factors.txt` includes TF factor annotation for each motifs. The file should be like a tsv file like below.

The first column should be motif name, the motif name should match with motif name in `pfm` file. The second column is gene symbol, the third column is datasource. This column is not important. The forth column is additional information for this factor. The factor is labeled with “Y” If factor information was confirmed by some evidence. Otherwise, the factor is labeled with “N”.

```
[52]: path_motif2factors = path.replace(".pfm", ".motif2factors.txt")

with open(path_motif2factors, "r") as f:
    for i, j in enumerate(f):
        print(j)
        if i>5:
            break
```

Motif	Factor	Evidence	Curated
MA0020.1_Dof2	Dof2	SELEX	Y
MA0021.1_Dof3	Dof3	SELEX	Y
MA0034.1_Gam1	Gam1	SELEX	Y
MA0044.1_HMG-1	HMG-1	SELEX	Y
MA0045.1_HMG-I/Y		HMG-I/Y SELEX	Y
MA0053.1_MNB1A	MNB1A	SELEX	Y

3.2 XXX.pfm

The second file, XXX.pfm. should includes motif pwm information. The file shoud be like below.

The motif name in this pfm file should exactly match with the motif name in motif2factor.txt file.

```
[55]: with open(path, "r") as f:
    for i, j in enumerate(f):
        print(j)
        if i>10:
            break

```

3.3 Load files as motif list

We can load files using `read_motifs` function in `gimmemotifs`.

First, please prepare two files, `XXX.motif2factors.txt` and `XXX.pfm`. in the same directly. If you have theses two file in a different place, we cannot use the `read_motifs` function.

Then use file path for `XXX.pfm` for the argument of `read_motifs` function.

```
[58]: from gimmemotifs.motif import read_motifs

# Check path for pfm file
print(path)

# Read motifs
motifs = read_motifs(path)

# Check first 10 motifs
motifs[:10]
```

```

MA0053.1_MNB1A_AAAGC,
MA0054.1_myb_Ph3_TAACnGTTw,
MA0064.1_PBF_AAAGY,
MA0082.1_squamosa_mC AwAwATrGwAAn,
MA0096.1_bZIP910_mTGACGT]
```

In another notebook, we introduce how to make `XXX.pfm` file and `XXX.motif2factors.txt` file. Pleas look at that if you want to make your motif data by yourself.

[Optional step 2] How to Make custom motifs for celloracle motif analysis

If you cannot find an appropriate motif dataset for your analysis and want to it by yourself. You can follow the instruction below. We introduce an example way to make motifs using [CisDB TF binding database](#).

0. Overview: How to Make custom motifs for celloracle motif scan.

In this notebook, we introduce how to make motif dataset for celloracle motif analysis. Celloracle uses list of motif object in `gimmemotifs` package. See `gimmemotifs` documentation for more details. (<https://gimmemotifs.readthedocs.io/en/master/api.html#>)

Here, we get motif data from CisBP (version2).<http://cisbp.ccbr.utoronto.ca>

We will extract motif information for a specific species and save as `XXX.pfm` and `XXX.motif2factors.txt` file. These files can be read with `read_motifs` function in `gimmemotifs`.

```
[1]: import numpy as np
import pandas as pd
import seaborn as sns
```

(continues on next page)

(continued from previous page)

```
import sys, os

import matplotlib.pyplot as plt
%matplotlib inline
plt.rcParams["figure.figsize"] = [20,10]

from gimmermotifs.motif import Motif, read_motifs
```

[]:

1. Download full dataset for TF dataset from CisBP database

Go the URL below for the download link for the latest data. <http://cisbp.ccbr.utoronto.ca/entireDownload.php>

1.2.3 Single-cell RNA-seq data preprocessing

Network analysis and simulation in celloracle will be performed using scRNA-seq data. The scRNA-seq data should include the components below.

- Gene expression matrix; mRNA counts before scaling and transformation.
- Clustering results.
- Dimensional reduction results.

In addition to these minimum requirements, we highly recommend doing these analyses below in the preprocessing step.

- Data quality check and cell/gene filtering.
- Normalization
- Identification of highly variable genes

We recommend processing scRNA-seq data using either Scanpy or Seurat. If you are not familiar with the general workflow of scRNA-seq data processing, please go to [the documentation for scanpy](#) and [the documentation for Seurat](#) before celloracle analysis.

If you already have preprocessed scRNA-seq data, which includes the necessary information above, you can skip this part.

A. scRNA-seq data preprocessing with scanpy

scanpy is a python library for the analysis of scRNA-seq data.

In this tutorial, we introduce an example of scRNA-seq preprocessing for celloracle with scanpy. We wrote the notebook based on [one of scanpy's tutorials](#) with some modifications.

The jupyter notebook files and data used in this tutorial are available [here](#).

Python notebook

0. Import libraries

```
[1]: import os
import matplotlib.pyplot as plt
import numpy as np
import pandas as pd
import scanpy as sc
```

```
[9]: %matplotlib inline
%config InlineBackend.figure_format = 'retina'
plt.rcParams["savefig.dpi"] = 300
plt.rcParams["figure.figsize"] = [6, 4.5]
```

1. Load data

In this notebook, we will show an example of how to process scRNA-seq data using a scRNA-seq data of hematopoiesis (Paul, F., Arkin, Y., Giladi, A., Jaitin, D. A., Kenigsberg, E., Keren-Shaul, H., et al. (2015). Transcriptional Heterogeneity and Lineage Commitment in Myeloid Progenitors. *Cell*, 163(7), 1663–1677. <http://doi.org/10.1016/j.cell.2015.11.013>). You can easily download this scRNA-seq data with a scanpy function.

Please change the code below if you want to use your data.

```
[3]: # Download dataset. You can change the code blow if you use another data.
adata = sc.datasets.paul15()
```

WARNING: In Scanpy 0.*, this returned logarithmized data. Now it returns non-
logarithmized data.

... storing 'paul15_clusters' as categorical
Trying to set attribute `'.uns` of view, making a copy.

2. Filtering

```
[4]: # Only consider genes with more than 1 count
sc.pp.filter_genes(adata, min_counts=1)
```

3. Normalization

```
[5]: # Normalize gene expression matrix with total UMI count per cell
sc.pp.normalize_per_cell(adata, key_n_counts='n_counts_all')
```

4. Identification of highly variable genes

Removing non-variable genes not only reduces the calculation time during the GRN reconstruction and simulation, but also improve the accuracy of GRN inference. We recommend using the top 2000~3000 variable genes.

```
[6]: # Select top 2000 highly-variable genes
filter_result = sc.pp.filter_genes_dispersion(adata.X,
                                              flavor='cell_ranger',
                                              n_top_genes=2000,
                                              log=False)

# Subset the genes
adata = adata[:, filter_result.gene_subset]

# Renormalize after filtering
sc.pp.normalize_per_cell(adata)

Trying to set attribute `'.obs` of view, making a copy.
```

5. Log transformation

We will do log transformation scaling because these are necessary for PCA, clustering, and differential gene calculations.

However, we also need non-transformed gene expression data in the celloracle analysis. Thus we need to keep raw count in anndata using the following command before the log transformation.

```
[7]: # keep raw cont data before log transformation
adata.raw = adata
adata.layers["raw_count"] = adata.raw.X.copy()

# Log transformation and scaling
sc.pp.log1p(adata)
sc.pp.scale(adata)
```

6. Dimensional reduction

Dimensional reduction is one of the most important parts of the scRNA-seq analysis. Celloracle needs dimensional reduction embeddings to simulate cell transition.

Please choose a proper algorithm for dimensional reduction so that the embedding appropriately represents the data structure. We recommend using one of these dimensional reduction algorithms (or trajectory inference algorithms); UMAP, tSNE, diffusion map, force-directed graph drawing or PAGA.

In this example, we use a combination of four algorithms; diffusion map, force-directed graph drawing, and PAGA.

```
[9]: # PCA
sc.tl.pca(adata, svd_solver='arpack')

[10]: # Diffusion map
sc.pp.neighbors(adata, n_neighbors=4, n_pcs=20)

sc.tl.diffmap(adata)
# Calculate neighbors again based on diffusionmap
sc.pp.neighbors(adata, n_neighbors=10, use_rep='X_diffmap')
```

7. Clustering

```
[11]: sc.tl.louvain(adata, resolution=0.8)
```

(Optional) Re-calculate Dimensional reduction graph

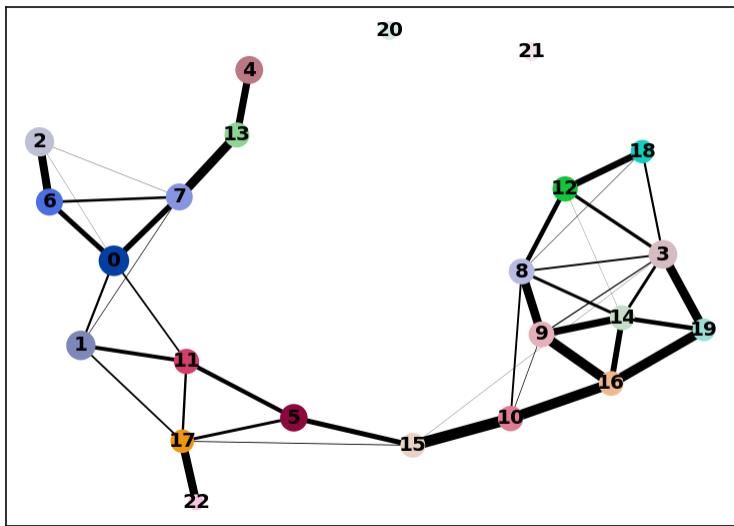

```
[12]: # PAGA graph construction
sc.tl.paga(adata, groups='louvain')
```

```
[13]: # Check current cluster name
cluster_list = adata.obs.louvain.unique()
cluster_list
```

```
[13]: [5, 2, 12, 13, 0, ..., 6, 20, 14, 15, 21]
Length: 23
Categories (23, object): [5, 2, 12, 13, ..., 20, 14, 15, 21]
```

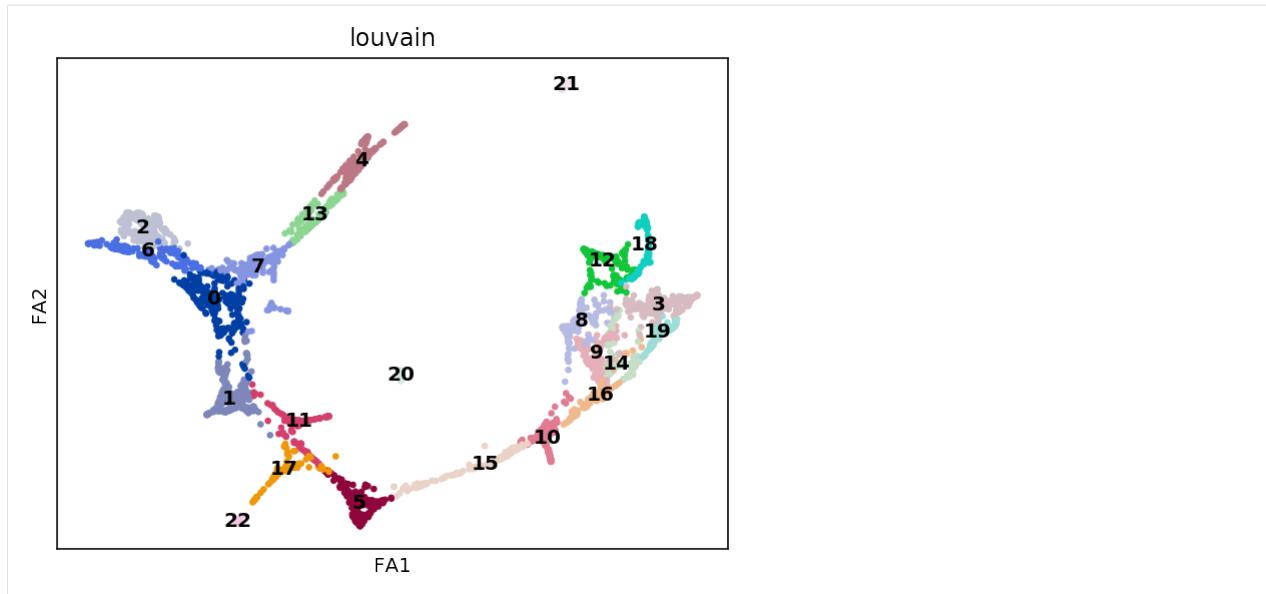

```
[14]: plt.rcParams["figure.figsize"] = [6, 4.5]
```

```
[15]: sc.pl.paga(adata)
```

```
[16]: sc.tl.draw_graph(adata, init_pos='paga', random_state=123)
```

```
[17]: sc.pl.draw_graph(adata, color='louvain', legend_loc='on data')
```

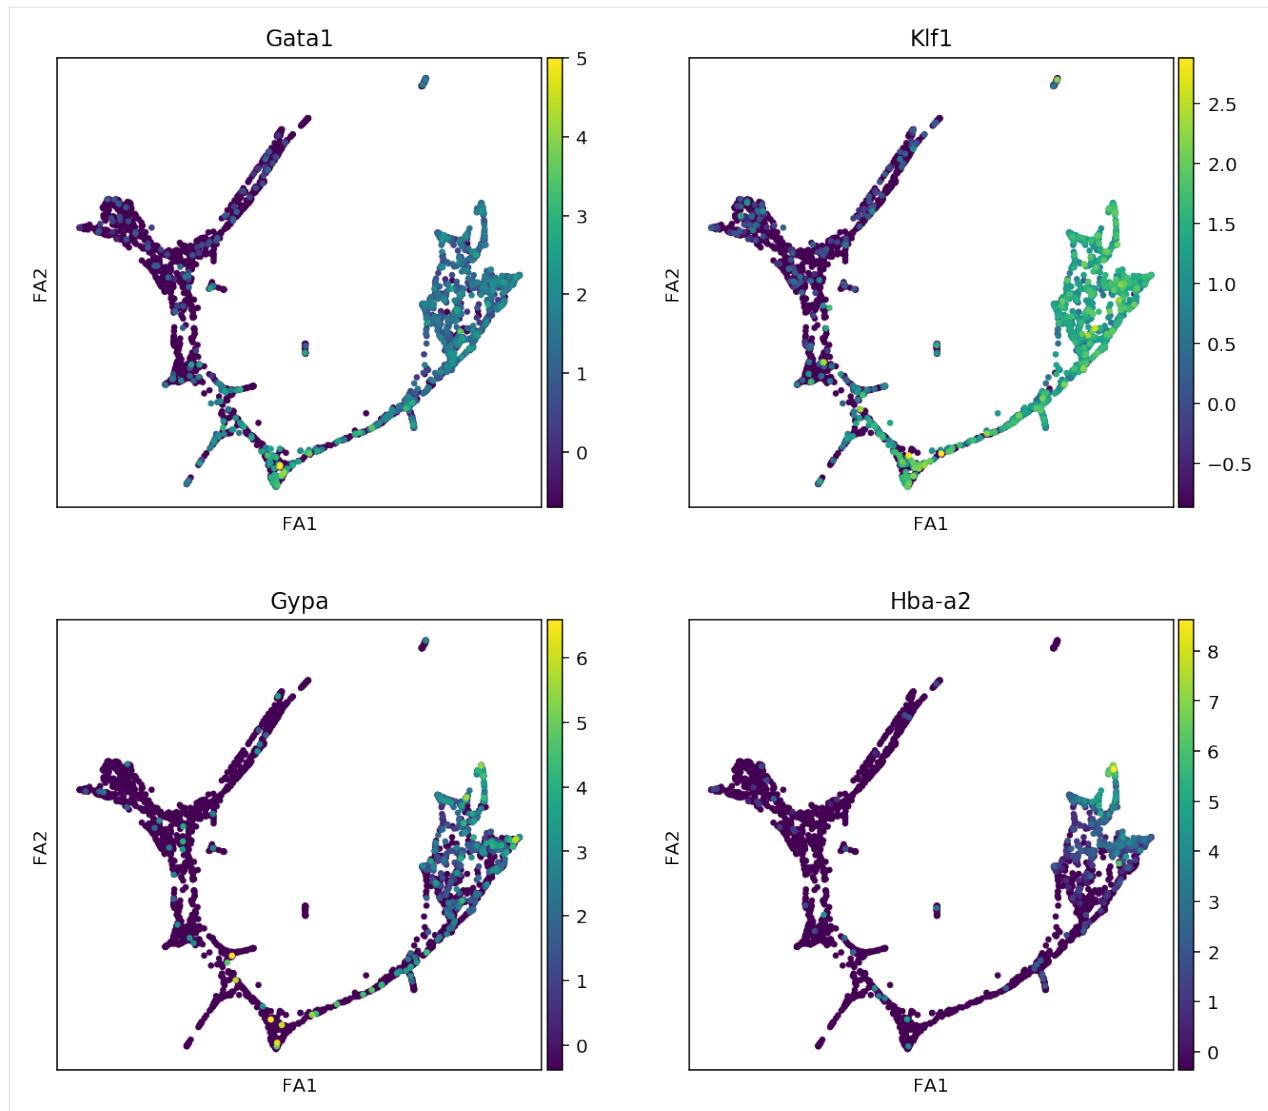

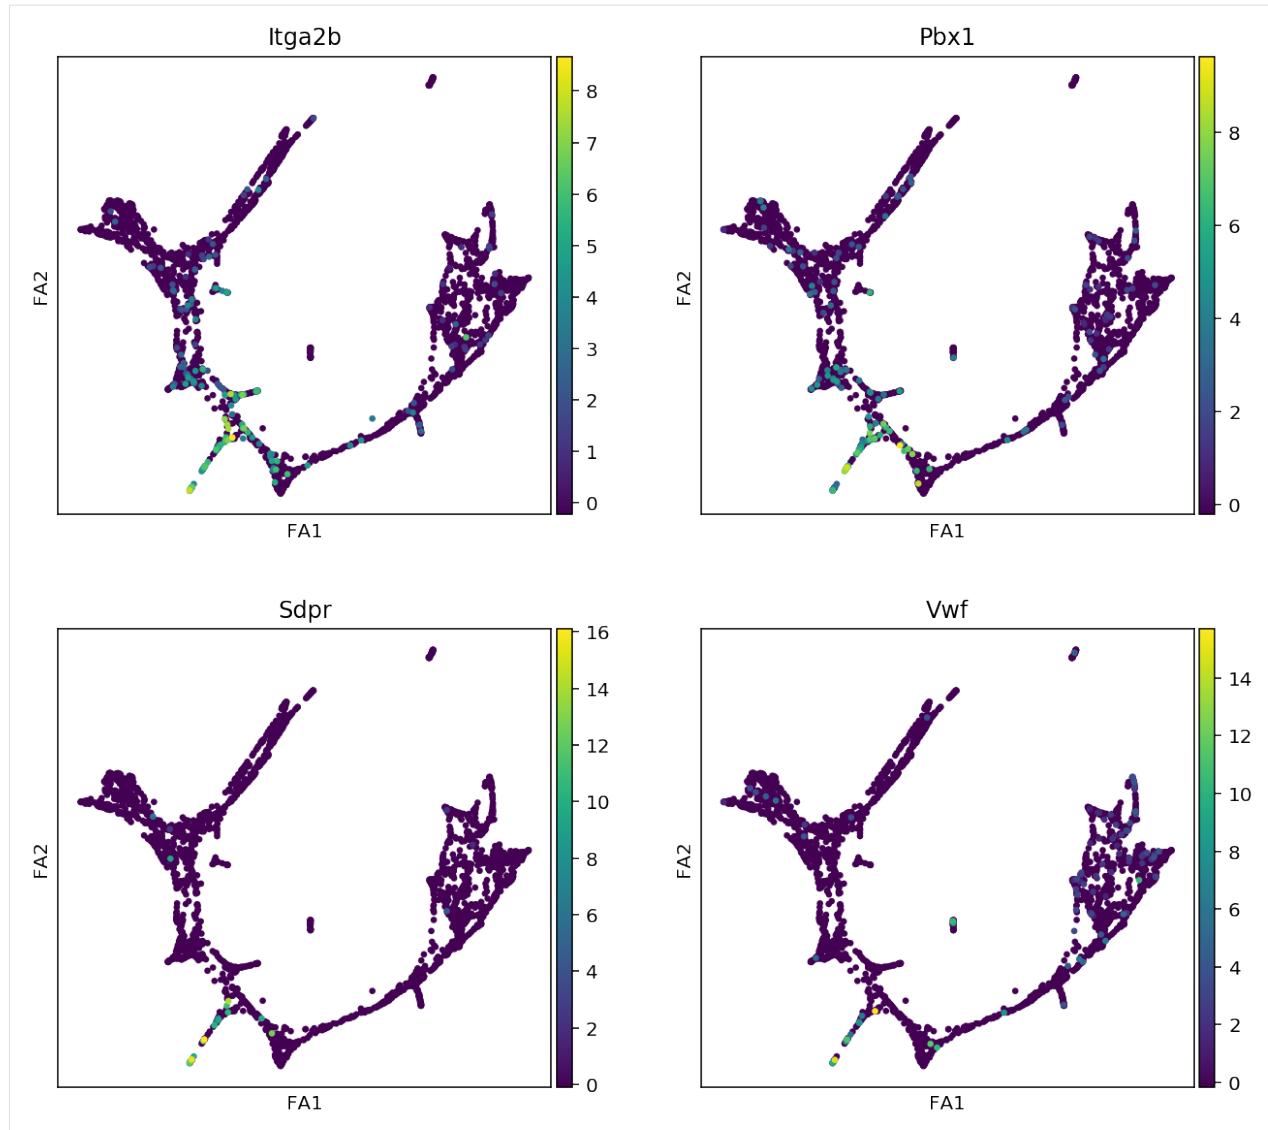

8. Check data

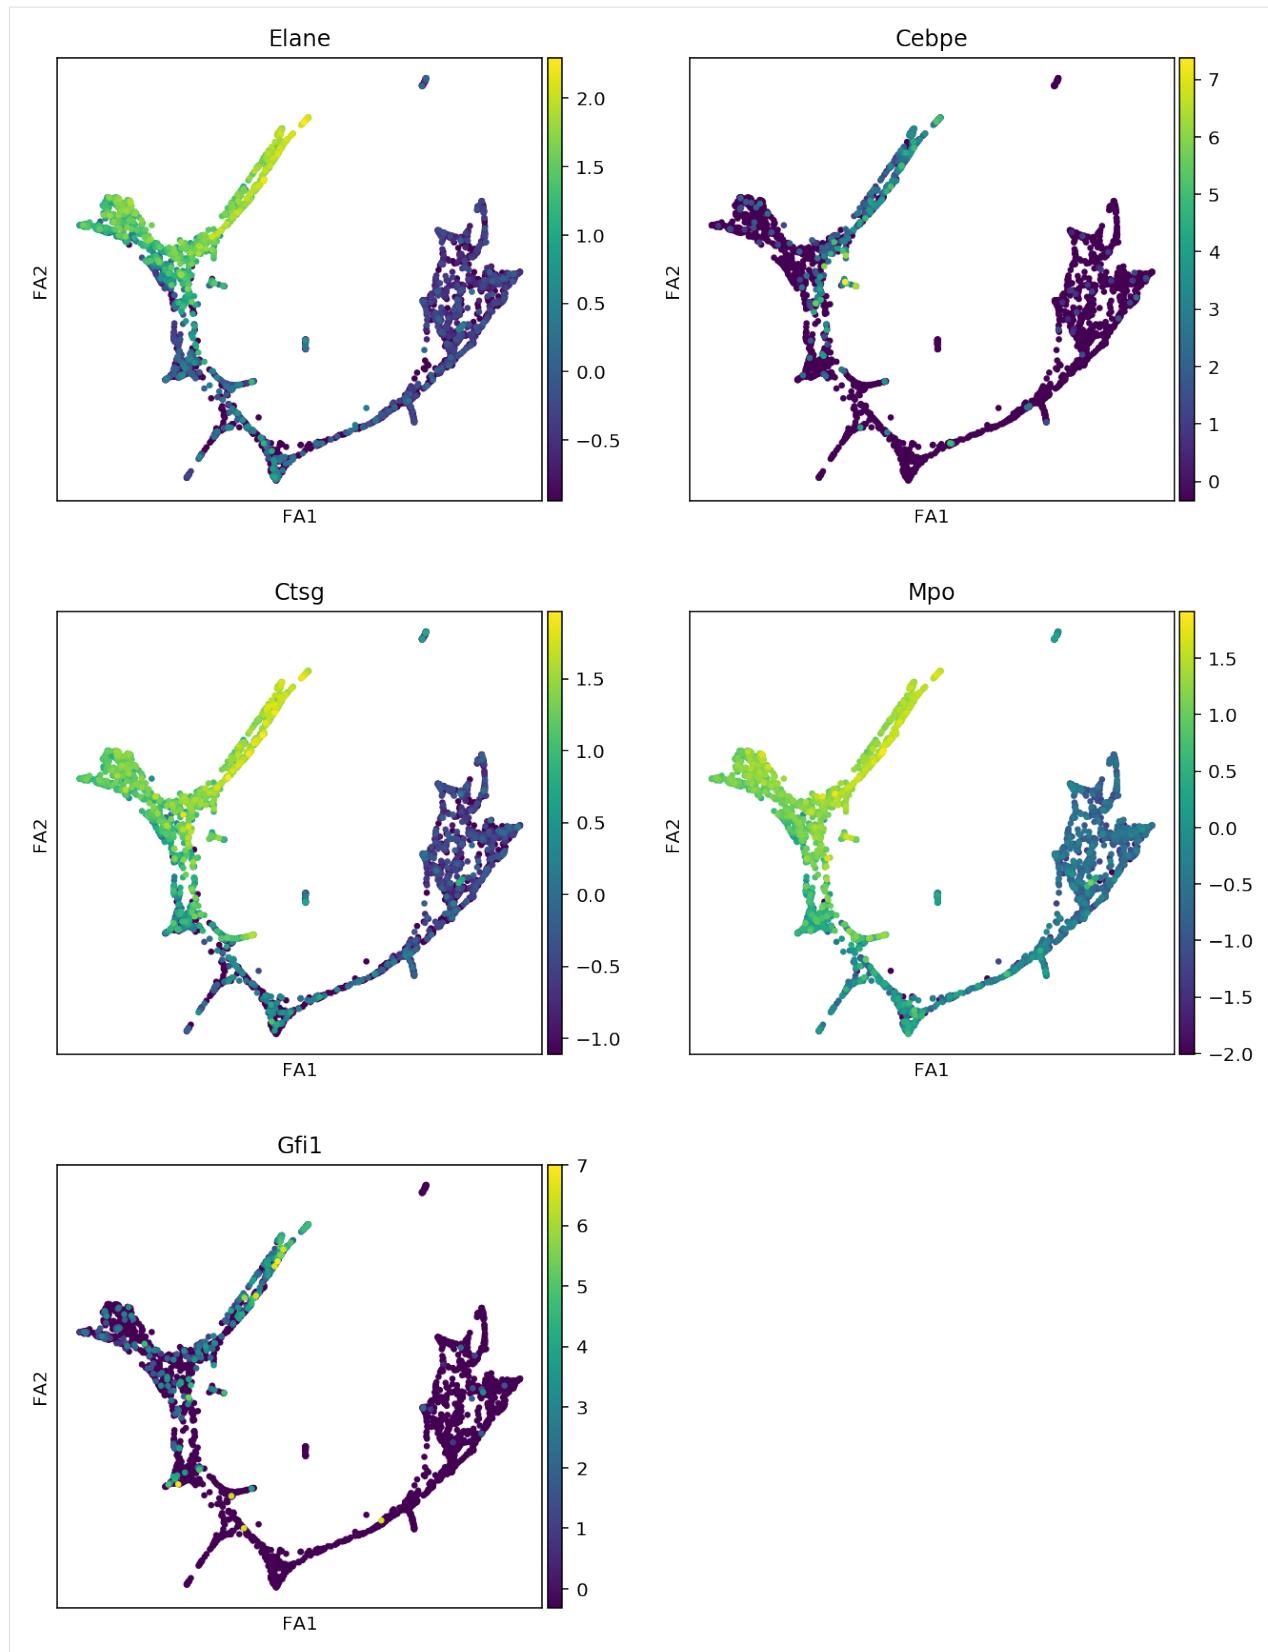

```
[18]: plt.rcParams["figure.figsize"] = [4.5, 4.5]

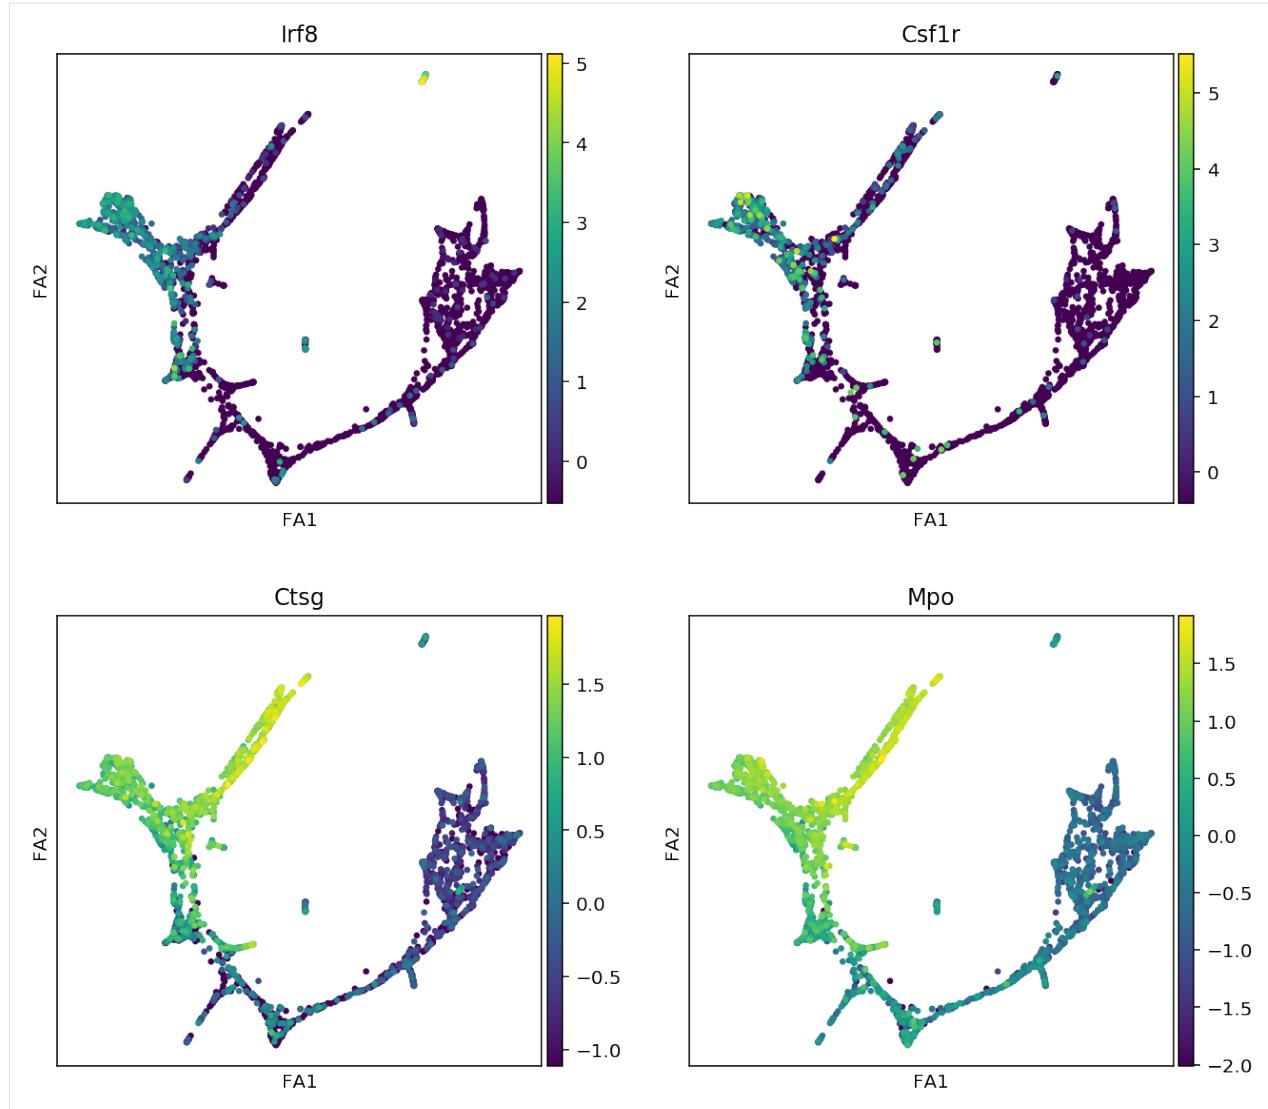

[19]: markers = {"Erythroids": ["Gata1", "Klf1", "Gypa", "Hba-a2"],
   "Megakaryocytes": ["Itga2b", "Pbx1", "Sdpr", "Vwf"],
   "Granulocytes": ["Elane", "Cebpe", "Ctsg", "Mpo", "Gfil"],
   "Monocytes": ["Irf8", "Csflr", "Ctsg", "Mpo"],
   "Mast_cells": ["Cma1", "Gzmb", "Kit"],
   "Basophils": ["Mcpt8", "Prss34"]
}

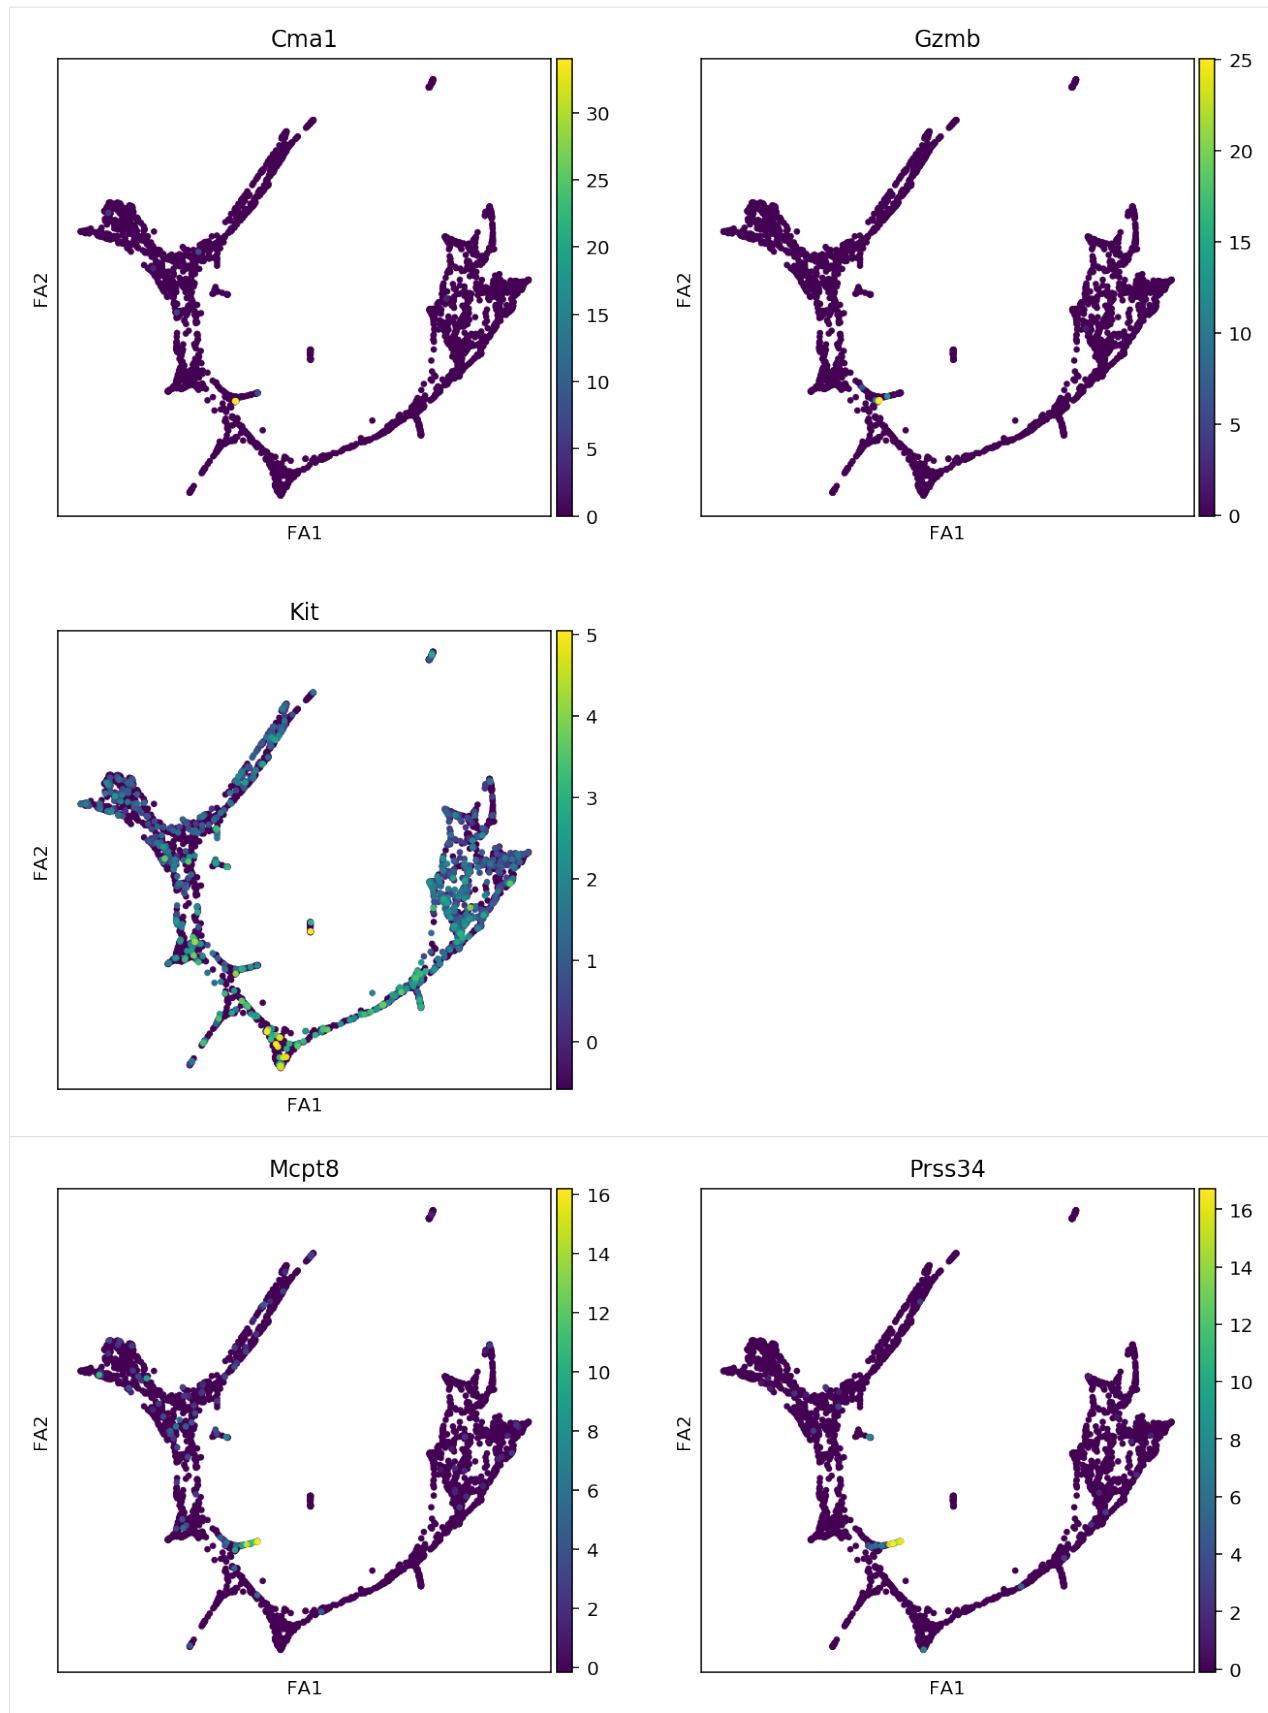

for cell_type, genes in markers.items():
    print(f"marker gene of {cell_type}")
    sc.pl.draw_graph(adata, color=genes, use_raw=False, ncols=2)
    plt.show()
```

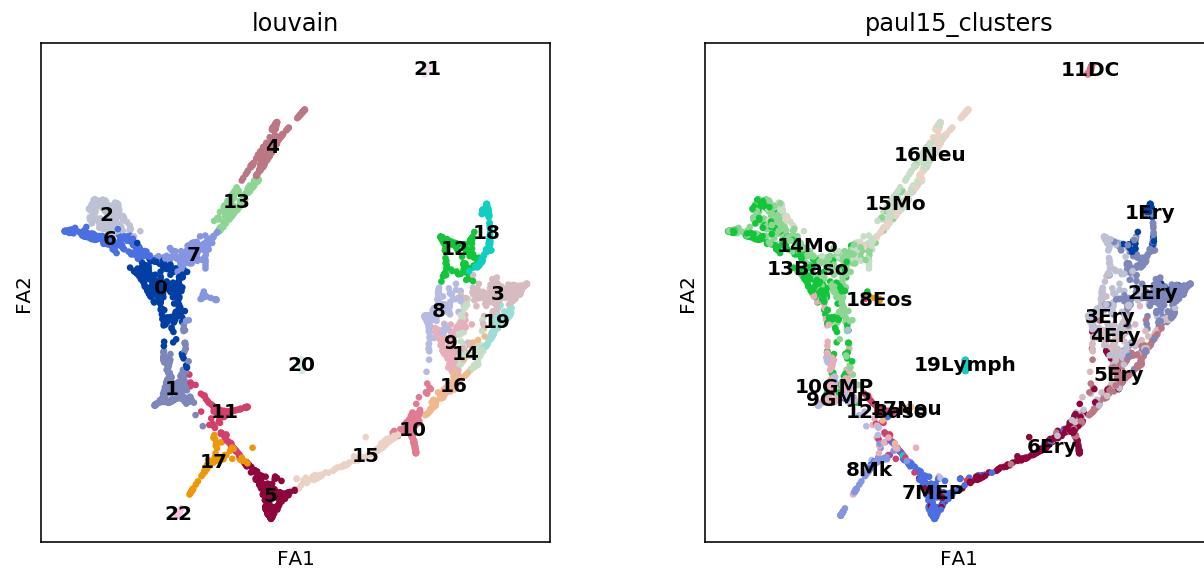

9. Make annotation for cluster

Based on the marker gene expression and previous reports, we will manually annotate each cluster. When using your own data, you will need to annotate the clusters appropriately.

```
[20]: sc.pl.draw_graph(adata, color=['louvain', 'paul15_clusters'],
                      legend_loc='on data')
```

```
[21]: # Check current cluster name
cluster_list = adata.obs.louvain.unique()
cluster_list
```

```
[21]: [5, 2, 12, 13, 0, ..., 6, 20, 14, 15, 21]
Length: 23
Categories (23, object): [5, 2, 12, 13, ..., 20, 14, 15, 21]
```

```
[22]: # Make annotation dictionary
annotation = {"MEP": [5],
              "Erythroids": [15, 10, 16, 9, 8, 14, 19, 3, 12, 18],
              "Megakaryocytes": [17, 22],
              "GMP": [11, 1],
              "late_GMP": [0],
              "Granulocytes": [7, 13, 4],
              "Monocytes": [6, 2],
              "DC": [21],
              "Lymphoid": [20]}

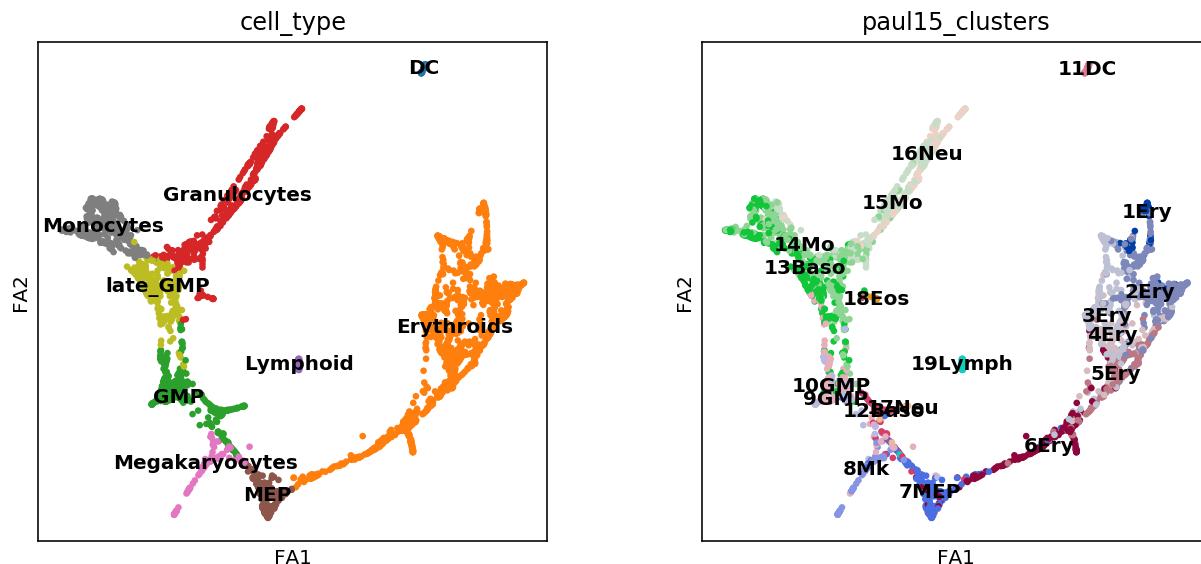

# change dictionary format
annotation_rev = {}
for i in cluster_list:
    for k in annotation:
        if int(i) in annotation[k]:
            annotation_rev[i] = k

# check dictionary
annotation_rev
```

```
[22]: {'5': 'MEP',

'21': 'DC'}
```

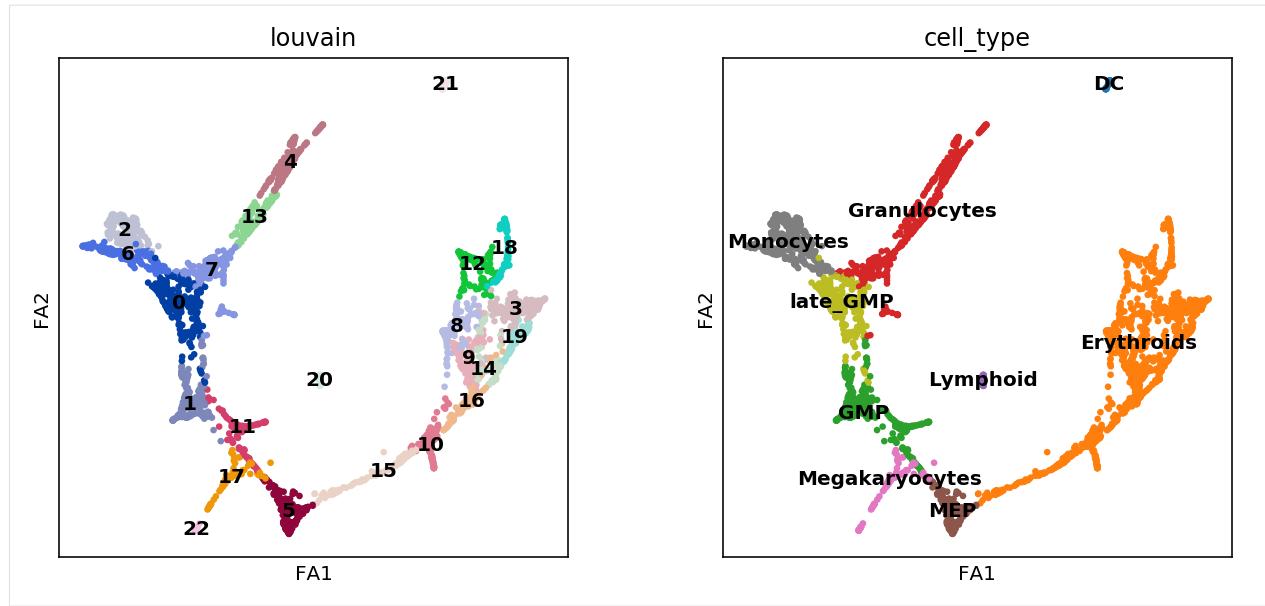

```
[23]: adata.obs["cell_type"] = [annotation_rev[i] for i in adata.obs.louvain]
```

```
[24]: # check results
sc.pl.draw_graph(adata, color=['cell_type', 'paul15_clusters'],
                 legend_loc='on data')
```

We'll make another annotation manually for each Louvain clusters.

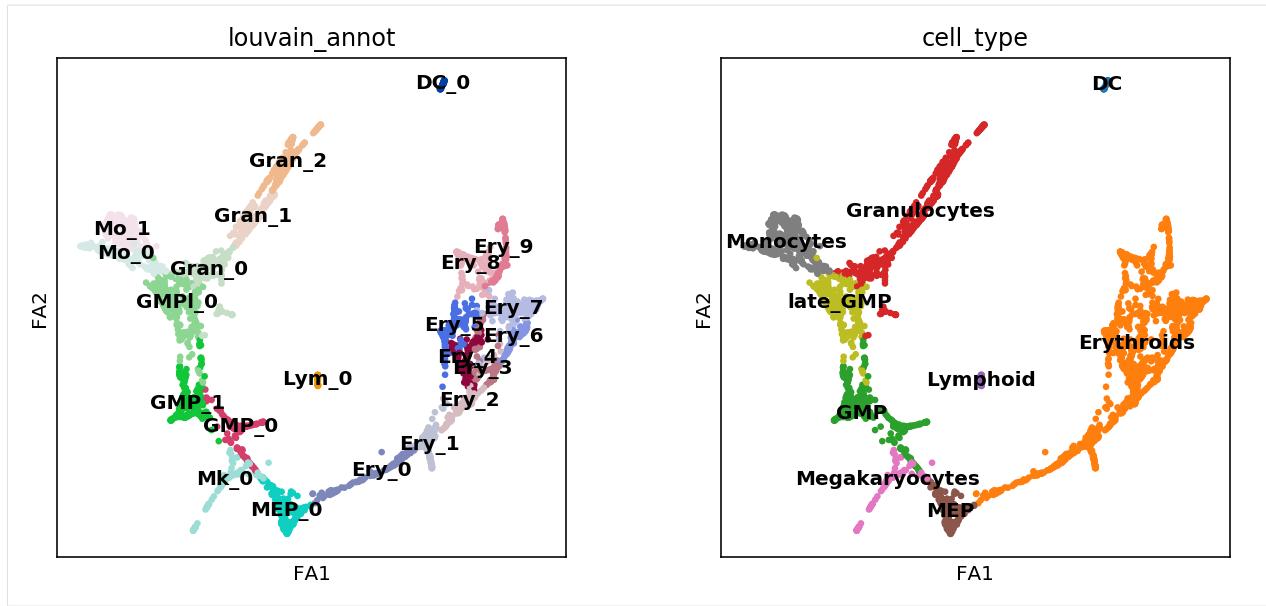

```
[25]: sc.pl.draw_graph(adata, color=['louvain', 'cell_type'],
                     legend_loc='on data')
```

```
[26]: annotation_2 = {'5': 'MEP_0',
                   '15': 'Ery_0',
                   '10': 'Ery_1',
                   '16': 'Ery_2',
                   '14': 'Ery_3',
                   '9': 'Ery_4',
                   '8': 'Ery_5',
                   '19': 'Ery_6',
                   '3': 'Ery_7',
                   '12': 'Ery_8',
                   '18': 'Ery_9',
                   '17': 'Mk_0',
                   '22': 'Mk_0',
                   '11': 'GMP_0',
                   '1': 'GMP_1',
                   '0': 'GMP_0',
                   '7': 'Gran_0',
                   '13': 'Gran_1',
                   '4': 'Gran_2',
                   '6': 'Mo_0',
                   '2': 'Mo_1',
                   '21': 'DC_0',
                   '20': 'Lym_0'}
```

```
[27]: adata.obs["louvain.annot"] = [annotation_2[i] for i in adata.obs.louvain]
```

```
[28]: # Check result
sc.pl.draw_graph(adata, color=['louvain.annot', 'cell_type'],
                 legend_loc='on data')
```

We've done several scRNA-preprocessing steps; filtering, normalization, clustering, and dimensional reduction. In the next step, we'll do the GRN inference, network analysis, and in silico simulation based on this information.

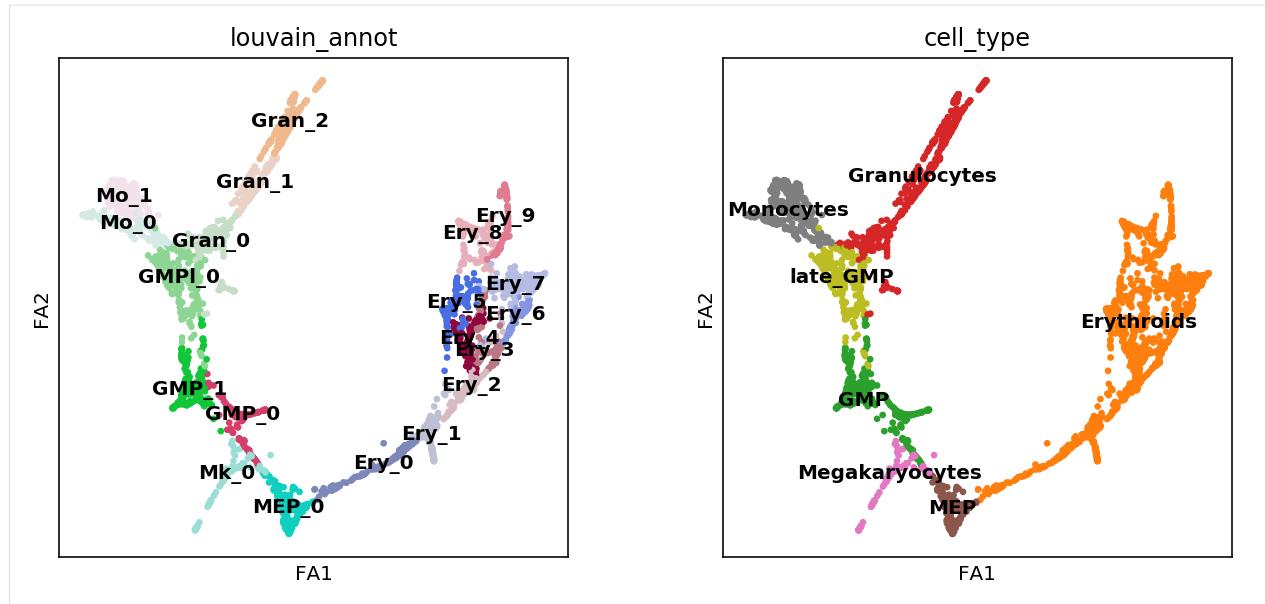

10. (Option) Subset cells

In this tutorial, we are using scRNA-seq data of hematopoiesis. In the latter part, we will focus on the cell fate decision in the myeloid lineage. So we will remove non-myeloid cell cluster; DC and Lymphoid cell cluster.

```
[29]: adata.obs.cell_type.unique()
[29]: [MEP, Monocytes, Erythroids, Granulocytes, late_GMP, GMP, Megakaryocytes, Lymphoid, DC]
Categories (9, object): [MEP, Monocytes, Erythroids, Granulocytes, ..., GMP, Megakaryocytes, Lymphoid, DC]
```

```
[30]: cell_of_interest = adata.obs.index[~adata.obs.cell_type.isin(["Lymphoid", "DC"])]
adata = adata[cell_of_interest, :]
```

```
[31]: # check result
sc.pl.draw_graph(adata, color=['louvain_annot', 'cell_type'],
                 legend_loc='on data')
```

11. Save data

```
[ ]: adata.write_h5ad("data/Paul_et al_15.h5ad")
```

B. scRNA-seq data preprocessing with Seurat

R notebook ... comming in the future update.

Note: If you use `Seurat` for preprocessing, you need to convert the scRNA-seq data (`Seurat` object) into `anndata` to analyze the data with `celloracle`. `celloracle` has a python API and command-line API to convert a `Seurat` object into an `anndata`. Please go to the documentation of `celloracle`'s API documentation for more information.

1.2.4 Network analysis

`celloracle` imports the scRNA-seq dataset and TF binding information to find active regulatory connections for all genes, generating sample-specific GRNs.

The inferred GRN is analyzed with several network algorithms to get various network scores. The network score is useful to identify key regulatory genes.

Celloracle reconstructs a GRN for each cluster, enabling us to compare GRNs to each other. It is also possible to analyze how the GRN changes over differentiation. The dynamics of the GRN structure can provide us insight into the context-dependent regulatory mechanisms.

The jupyter notebook files and data used in this tutorial are available [here](#).

Python notebook

0. Import libraries

```
[1]: # 0. Import

import os
import sys

import matplotlib.pyplot as plt
import numpy as np
import pandas as pd
import scanpy as sc
import seaborn as sns
```

```
[2]: import celloracle as co
co.__version__
[2]: '0.6.11'
```

```
[3]: # visualization settings
%config InlineBackend.figure_format = 'retina'
%matplotlib inline

plt.rcParams['figure.figsize'] = [6, 4.5]
plt.rcParams["savefig.dpi"] = 300
```

0.1. Check installation

Celloracle uses some R libraries in network analysis. Please make sure that all dependent R libraries are installed on your computer. You can test the installation with the following command.

```
[4]: co.test_R_libraries_installation()

R path: /usr/bin/R
checking R library installation: igraph -> OK
checking R library installation: linkcomm -> OK
checking R library installation: rnetcarto -> OK
```

0.2. Make a folder to save graph

```
[8]: save_folder = "figures"
os.makedirs(save_folder, exist_ok=True)
```

1. Load data

1.1. Load processed gene expression data (anndata)

Please refer to the previous notebook in the tutorial for an example of how to process scRNA-seq data.

```
[9]: # Load data. !!Replace the data path below when you use another data.
# adata = sc.read_h5ad("DATAPATH")

# Here, we will use a hematopoiesis data by Paul 2015.
# You can load preprocessed data using a celloracle function as follows.
adata = co.data.load_Paul2015_data()
adata
```

```
[9]: AnnData object with n_obs × n_vars = 2671 × 1999
      obs: 'paul15_clusters', 'n_counts_all', 'n_counts', 'louvain', 'cell_type',
      ↪'louvain_annot', 'dpt_pseudotime'
      var: 'n_counts'
      uns: 'cell_type_colors', 'diffmap_evals', 'draw_graph', 'iroot', 'louvain',
      ↪'louvain_annot_colors', 'louvain_colors', 'louvain_sizes', 'neighbors', 'paga',
      ↪'paul15_clusters_colors', 'pca'
      obsm: 'X_diffmap', 'X_draw_graph_fa', 'X_pca'
      varm: 'PCs'
      layers: 'raw_count'
      obsp: 'connectivities', 'distances'
```

1.2. (Optional step) Downsampling

If your scRNA-seq data includes more than 20K cells, I recommend doing downsampling. It is because the later simulation process will require large amount of memory if you have large data.

Also, please pay attention to the number of genes. If you are following the instruction in the previous tutorial notebook, the scRNA-seq data should include only top 2~3K variable genes. If you have more than 3K genes, it might cause problems in the later steps.

```
[16]: print(f"Cell number is :{adata.shape[0]}")
print(f"Gene number is :{adata.shape[1]}")
```

```
Cell number is :2671
Gene number is :1999
```

```
[17]: # Random downsampling into 30K cells if the anndata include more than 30 K cells.
n_cells_downsample = 30000

if adata.shape[0] > n_cells_downsample:
    # Let's downsample into 30K cells
    sc.pp.subsample(adata, n_obs=n_cells_downsample, random_state=123)
```

```
[18]: print(f"Cell number is :{adata.shape[0]}")
```

```
Cell number is :2671
```

1.2. Load TF data.

For the GRN inference, celloracle needs TF information, which contains lists of the regulatory candidate genes. There are several ways to make such TF information. We can generate TF information from scATAC-seq data or bulk ATAC-seq data. Please refer to the first step of the tutorial for the details of this process.

If you do not have your scATAC-seq data, you can use some built-in data in celloracle. The built-in TFinfo wqs made using various tissue/cell-types from the mouse ATAC-seq atlas dataset (<http://atlas.gs.washington.edu/mouse-atac/>).

You can load and use the data with the following command.

```
[12]: # Load TF info which was made from mouse cell atlas dataset.
TFinfo_df = co.data.load_TFinfo_df_mm9_mouse_atac_atlas()

# Check data
TFinfo_df.head()
```

```
[5 rows x 1095 columns]
```

2. Initiate Oracle object

Celloracle has a custom called Oracle. We can use Oracle for the data preprocessing and GRN inference steps. The Oracle object stores all of necessary information and does the calculations with its internal functions. We instantiate an Oracle object, then input the gene expression data (anndata) and a TFinfo into the Oracle object.

```
[19]: # Instantiate Oracle object
oracle = co.Oracle()
```

2.1. load gene expression data into oracle object.

When you load a scRNA-seq data, please enter the name of clustering data and dimensional reduction data. The clustering data should be stored in the attribute of “obs” in the anndata. Dimensional reduction data suppose to be stored in the attribute of “obsm” in the anndata. You can check these data by the following command.

If you are not familiar with anndata, please look at the documentation of annata (<https://anndata.readthedocs.io/en/stable/>) or Scanpy (<https://scanpy.readthedocs.io/en/stable/>).

For the celloracle analysis, the anndata shoud include (1) gene expression count, (2) clustering information, (3) trajectory (dimensional reduction embeddings) data. Please refer to another notebook for more information on anndata preprocessing.

```
[20]: # show data name in anndata
print("metadata columns : ", list(adata.obs.columns))
print("dimensional reduction: ", list(adata.obsm.keys()))

metadata columns : ['paul15_clusters', 'n_counts_all', 'n_counts', 'louvain', 'cell_
↪type', 'louvain_annot', 'dpt_pseudotime']
dimensional reduction: ['X_diffmap', 'X_draw_graph_fa', 'X_pca']
```

```
[21]: # In this notebook, we use raw mRNA count as an input of Oracle object.
adata.X = adata.layers["raw_count"].copy()

# Instantiate Oracle object.
oracle.import_anndata_as_raw_count(adata=adata,
                                    cluster_column_name="louvain_annot",
                                    embedding_name="X_draw_graph_fa")
```

2.2. Load TFinfo into oracle object

```
[22]: # You can load TF info dataframe with the following code.
oracle.import_TF_data(TF_info_matrix=TFinfo_df)

# Alternatively, if you saved the information as a dictionary, you can use the code_
↪below.
# oracle.import_TF_data(TFdict=TFinfo_dictionary)
```

2.3. (Optional) Add TF info manually

While we mainly use TF info data made from scATAC-seq data, we can also add additional information about the TF-target gene pair manually.

For example, if there is a study or database that includes specific TF-target pairs, you can use such information in the following way.

2.3.1. Make TF info dictionary manually

Here, we will introduce how to add TF binding information.

We will start with TF binding data from supplemental table 4 in (<http://doi.org/10.1016/j.cell.2015.11.013>).

In order to import TF data into the Oracle object, we need to convert them into a python dictionary. The dictionary keys will be the target genes, and the values will be the regulatory candidate TFs.

```

```
[24]: # Make dictionary: dictionary Key is TF, dictionary Value is list of target genes
TF_to_TG_dictionary = {}

for TF, TGs in zip(Paul_15_data.TF, Paul_15_data.Target_genes):
    # convert target gene to list
    TG_list = TGs.replace(" ", "").split(",")
    # store target gene list in a dictionary
    TF_to_TG_dictionary[TF] = TG_list

# We have to make a dictionary, in which a Key is Target gene and value is TF.
# We invert the dictionary above using a utility function in celloracle.
TG_to_TF_dictionary = co.utility.inverse_dictionary(TF_to_TG_dictionary)
```

```
HBox(children=(FloatProgress(value=0.0, max=178.0), HTML(value='')))
```

2.3.2. Add TF information dictionary into the oracle object

```
[25]: # Add TF information
oracle.addTFinfo_dictionary(TG_to_TF_dictionary)
```

3. Knn imputation

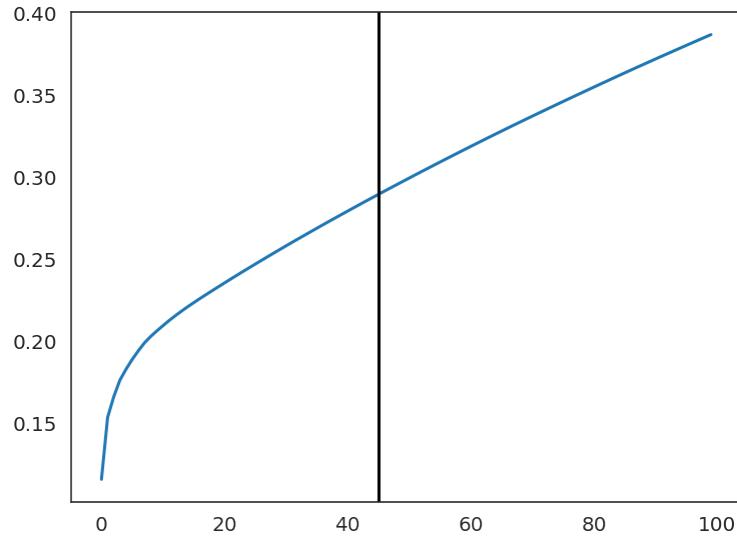

Celloracle uses almost the same strategy as velocyto for visualizing cell transitions. This process requires KNN imputation in advance.

For the KNN imputation, we need PCA and PC selection first.

3.1. PCA

```
[26]: # Perform PCA
oracle.perform_PCA()

# Select important PCs
plt.plot(np.cumsum(oracle.pca.explained_variance_ratio_) [:100])
n_comps = np.where(np.diff(np.diff(np.cumsum(oracle.pca.explained_variance_ratio_)) > 0.002)) [0] [0]
plt.axvline(n_comps, c="k")
print(n_comps)
n_comps = min(n_comps, 50)
```

3.2. KNN imputation

Estimate the optimal number of nearest neighbors for KNN imputation.

```
[27]: n_cell = oracle.adata.shape[0]
print(f"cell number is :{n_cell}")
cell number is :2671
```

```
[28]: k = int(0.025*n_cell)
print(f"Auto-selected k is :{k}")
Auto-selected k is :66
```

```
[29]: oracle.knn_imputation(n_pca_dims=n_comps, k=k, balanced=True, b_sight=k*8,
                           b_maxl=k*4, n_jobs=4)
```

4. Save and Load.

Celloracle has some custom-classes: Links, Oracle and TFinfo. You can save such an object using “to_hdf5”.

Please use “load_hdf5” function to load the file.

```
[30]: # Save oracle object.
oracle.to_hdf5("Paul_15_data.celloracle.oracle")
```

```
[31]: # Load file.
#oracle = co.load_hdf5("Paul_15_data.celloracle.oracle")
```

5. GRN calculation

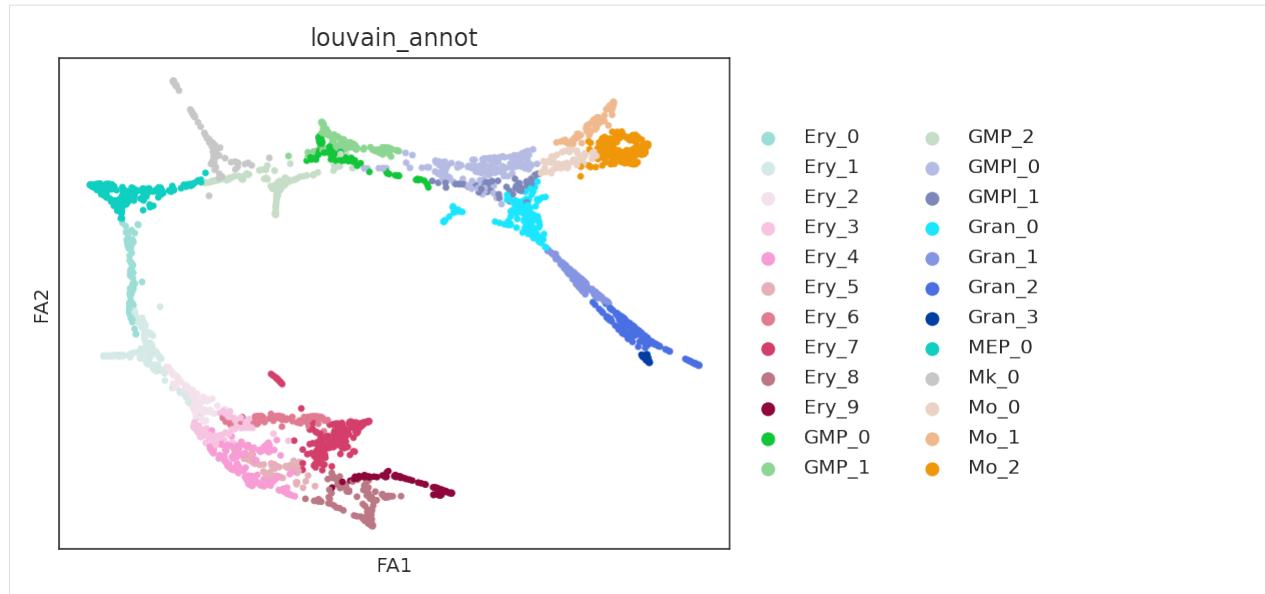

The next step is constructing a cluster-specific GRN for all clusters.

You can calculate GRNs with the “get_links” function, and the function returns GRNs as a Links object. The Links object stores inferred GRNs and the corresponding metadata. You can do network analysis with the Links object.

The GRN will be calculated for each cluster/sub-group. In the example below, we construct GRN for each unit of the “louvain_annot” clustering.

The GRNs can be calculated at any arbitrary unit as long as the clustering information is stored in anndata.

```
[32]: # check data
sc.pl.draw_graph(oracle.adata, color="louvain_annot")
```

5.1. Get GRNs

```
[ ]: %%time
# Calculate GRN for each population in "louvain_annot" clustering unit.
# This step may take long time. (~30 minutes)
links = oracle.get_links(cluster_name_for_GRN_unit="louvain_annot", alpha=10,
                           verbose_level=10, test_mode=False)
```

5.2. (Optional) Export GRNs

Although celloracle has many functions for network analysis, you can analyze GRNs by hand if you choose. The raw GRN data is stored in the attribute of “links_dict”.

For example, you can get the GRN for the “Ery_0” cluster with the following commands.

```
[34]: links.links_dict.keys()
[34]: dict_keys(['Ery_0', 'Ery_1', 'Ery_2', 'Ery_3', 'Ery_4', 'Ery_5', 'Ery_6', 'Ery_7',
   ↪ 'Ery_8', 'Ery_9', 'GMP_0', 'GMP_1', 'GMP_2', 'GMP1_0', 'GMP1_1', 'Gran_0', 'Gran_1',
   ↪ 'Gran_2', 'Gran_3', 'MEP_0', 'Mk_0', 'Mo_0', 'Mo_1', 'Mo_2'])
```

```
[35]: links.links_dict["Ery_0"]
[35]:      source      target  coef_mean  coef_abs          p    -logp

```

[74472 rows x 6 columns]

You can export the file as follows.

```
[36]: # Set cluster name
cluster = "Ery_0"

# Save as csv
links.links_dict[cluster].to_csv(f"raw_GRN_for_{cluster}.csv")
```

5.3. (Optional) Change order

The links object has a color information in an attribute, “palette”. This information is used for the visualization

The sample will be visualized in that order. Here we can change the order.

```
[43]: # Show the contents of palette
links.palette
```

```
[43]: palette
Ery_0      #9CDED6
Ery_1      #D5EAE7

```

6. Network preprocessing

6.1. Filter network edges

Celloracle utilizes bagging ridge or Bayesian ridge regression to infer gene regulatory networks. These methods provide a network edge strength as a distribution rather than a point value. We can use the distribution to know the certainness of the connection.

We filter the network edges as follows.

- (1) Remove uncertain network edges based on the p-value.
- (2) Remove weak network edge. In this tutorial, we pick up the top 2000 edges in terms of network strength.

The raw network data is stored as an attribute, “links_dict,” while filtered network data is stored in “filtered_links.” Thus the filtering function keeps raw network information rather than overwriting the data. You can come back to the filtering process to filter the data with different parameters if you want.

```
[47]: links.filter_links(p=0.001, weight="coef_abs", thread_number=2000)
```

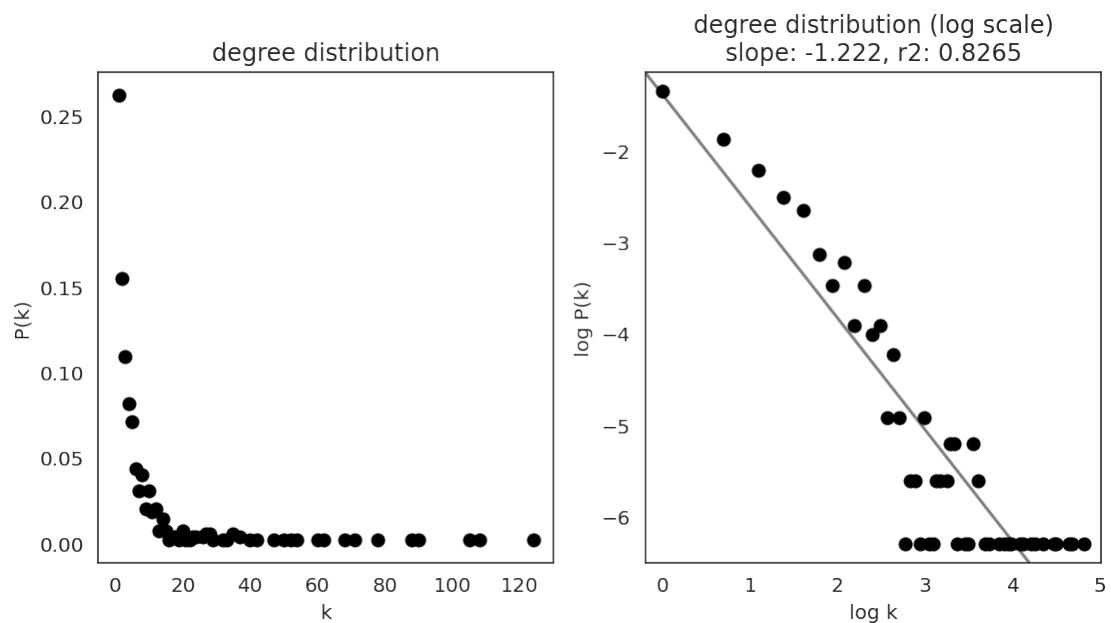

6.2. Degree distribution

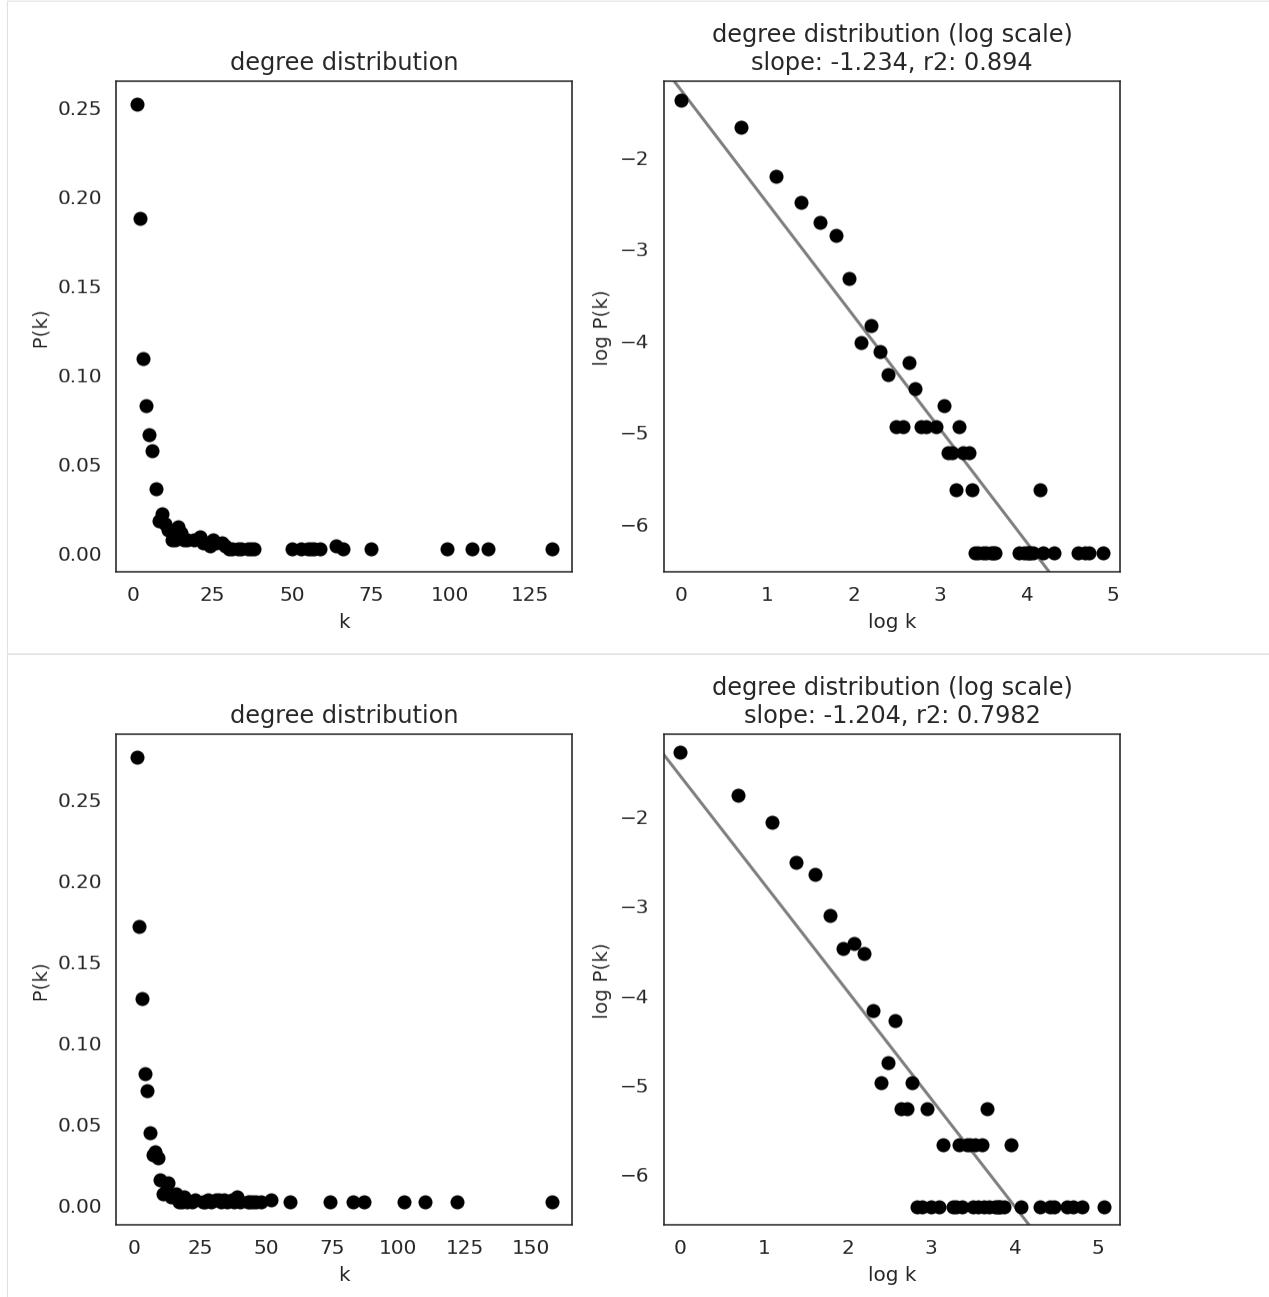

In the first step, we examine the network degree distribution. Network degree, which is the number of edges for each node, is one of the important metrics used to investigate the network structure (https://en.wikipedia.org/wiki/Degree_distribution).

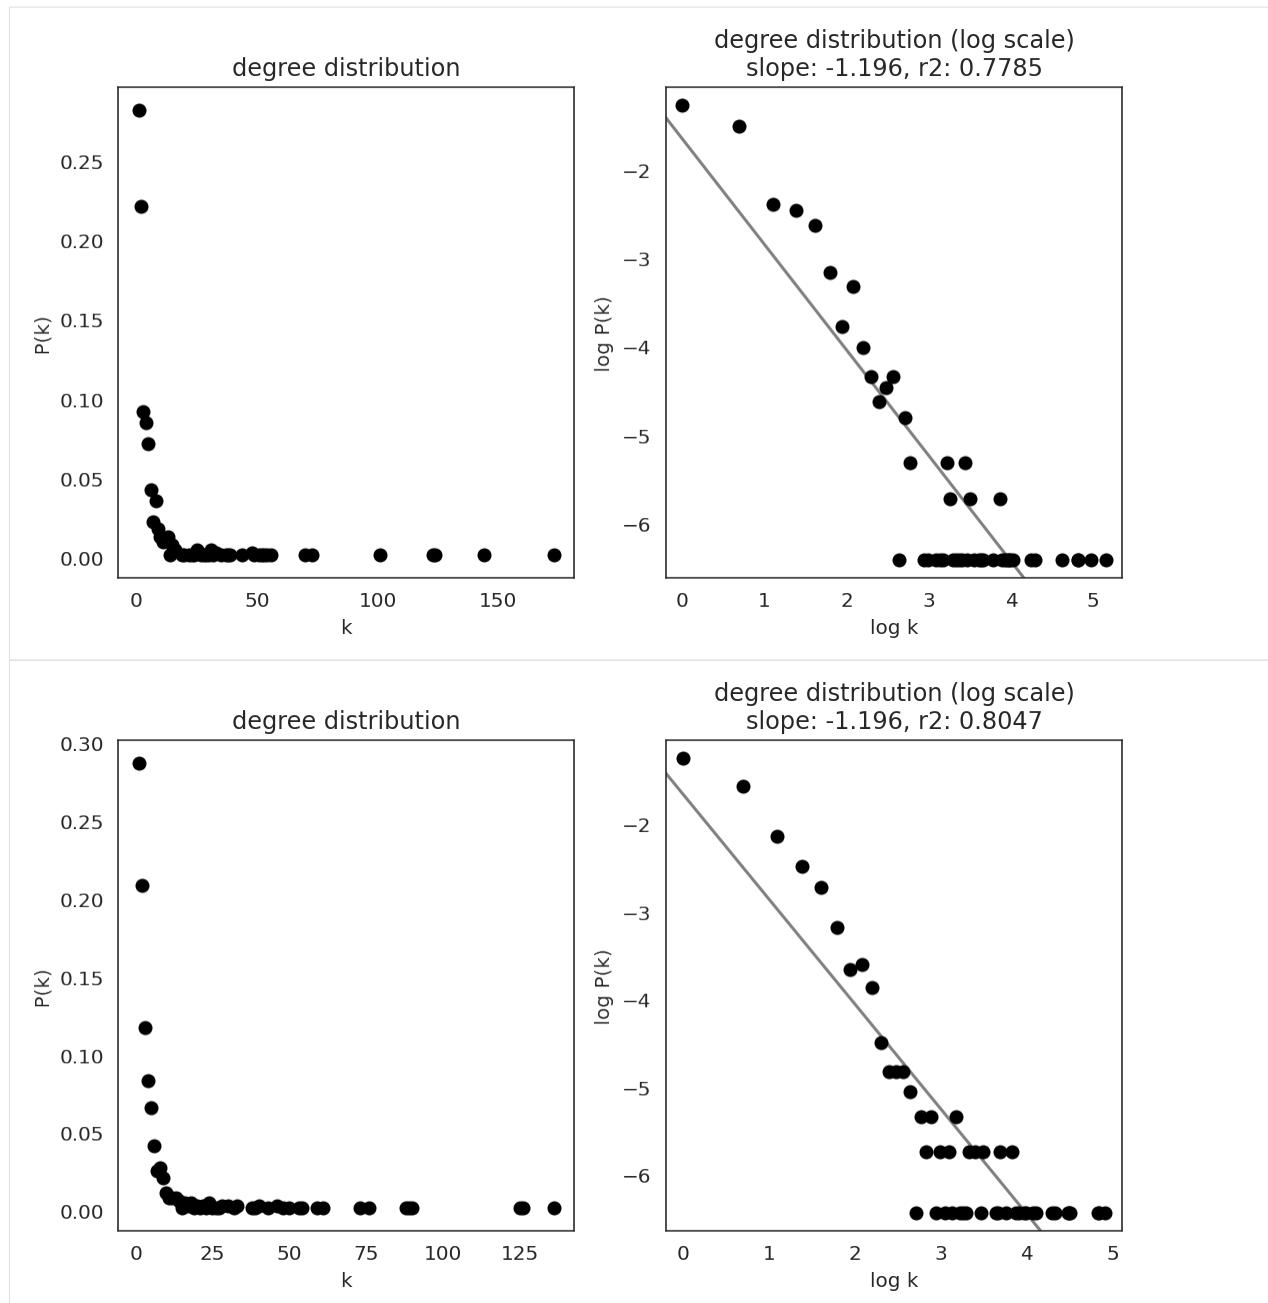

Please keep in mind that the degree distribution may change depending on the filtering threshold.

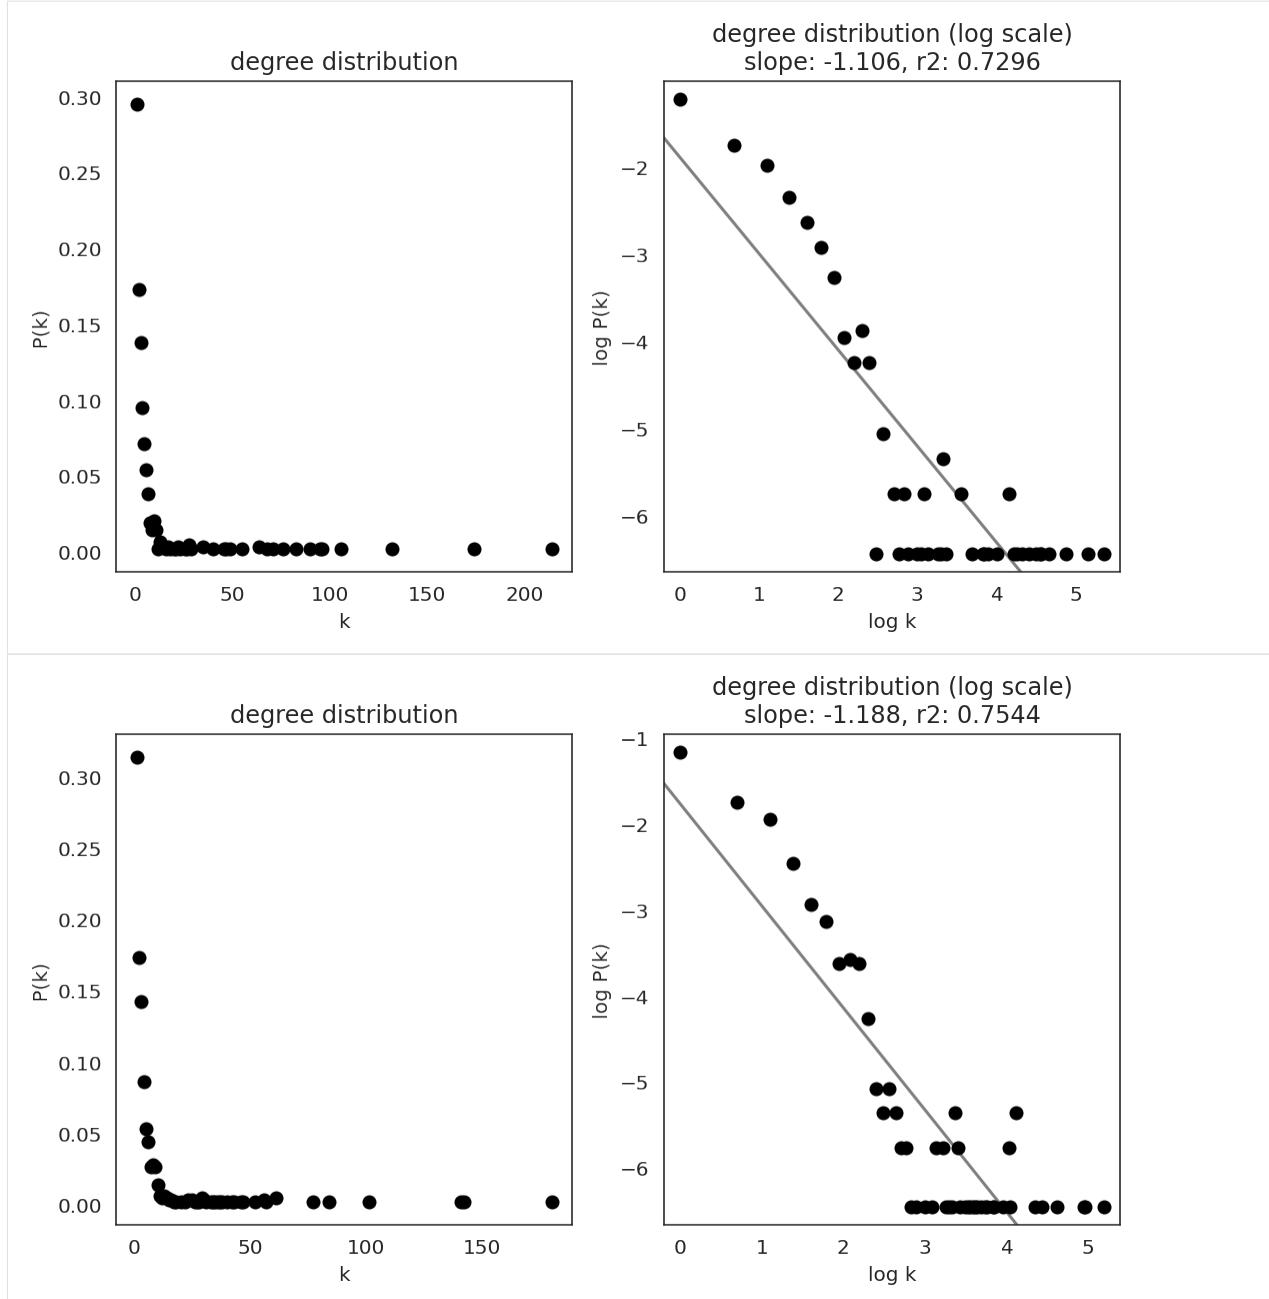

```
[48]: plt.rcParams["figure.figsize"] = [9, 4.5]
```

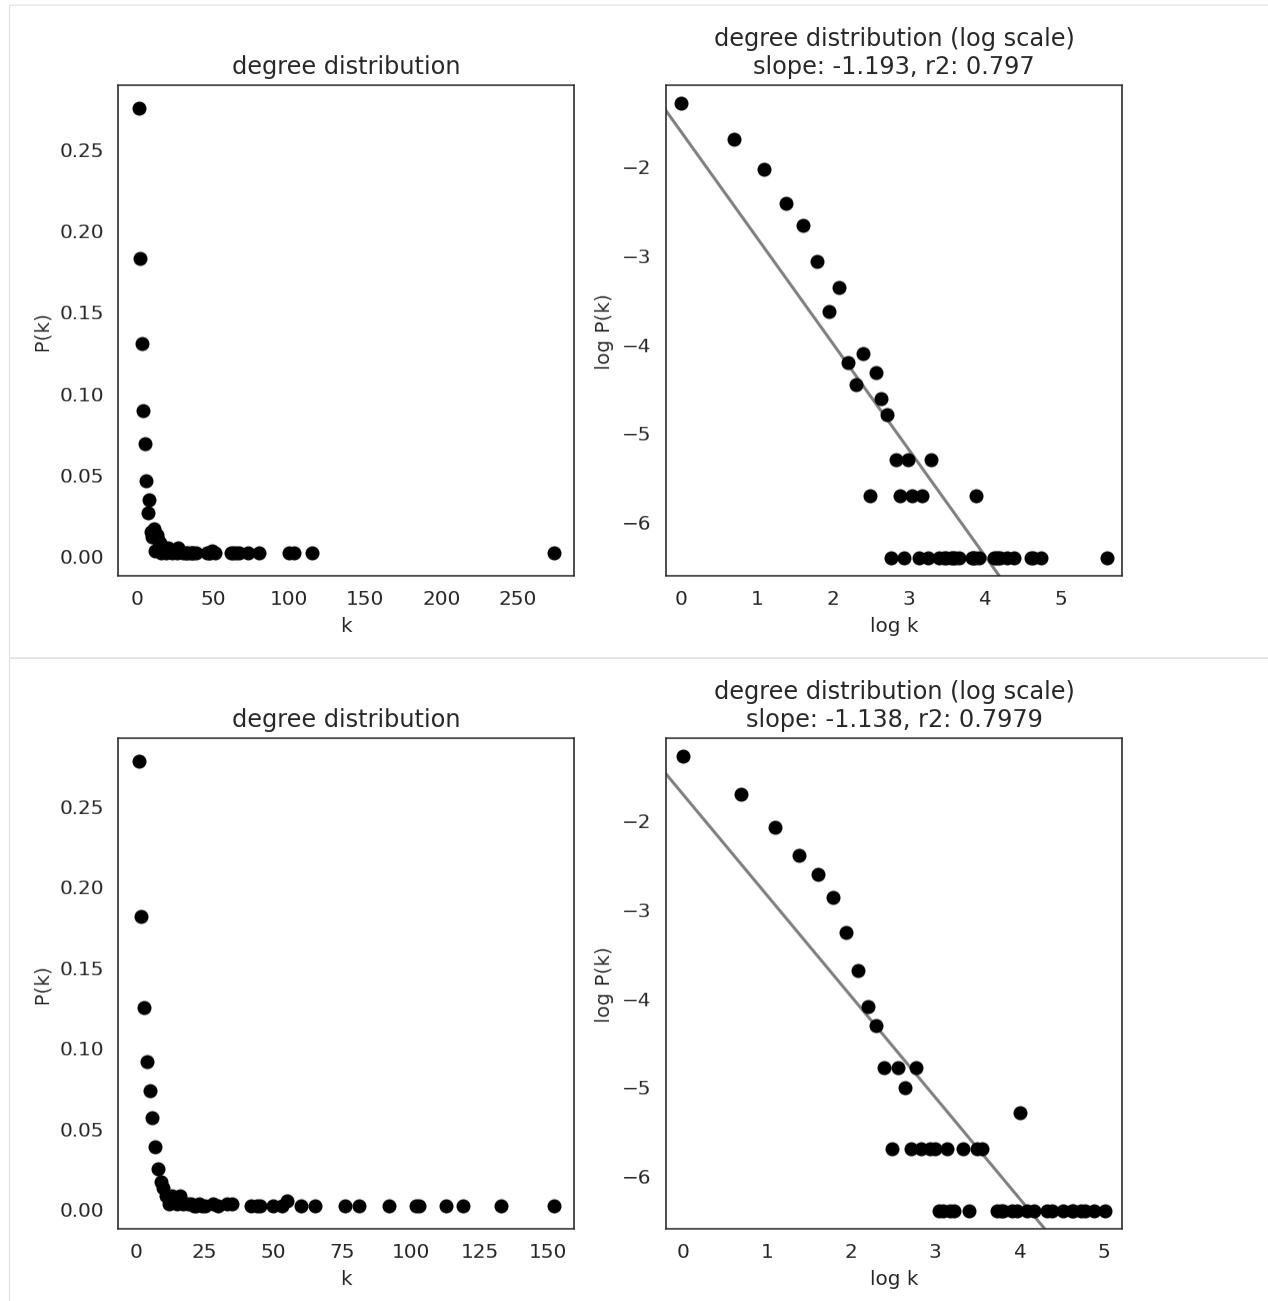

```
[49]: links.plot_degree_distributions(plot_model=True,
                                     #save=f'{save_folder}/degree_
                                     ↪distribution/',
                                     )
```

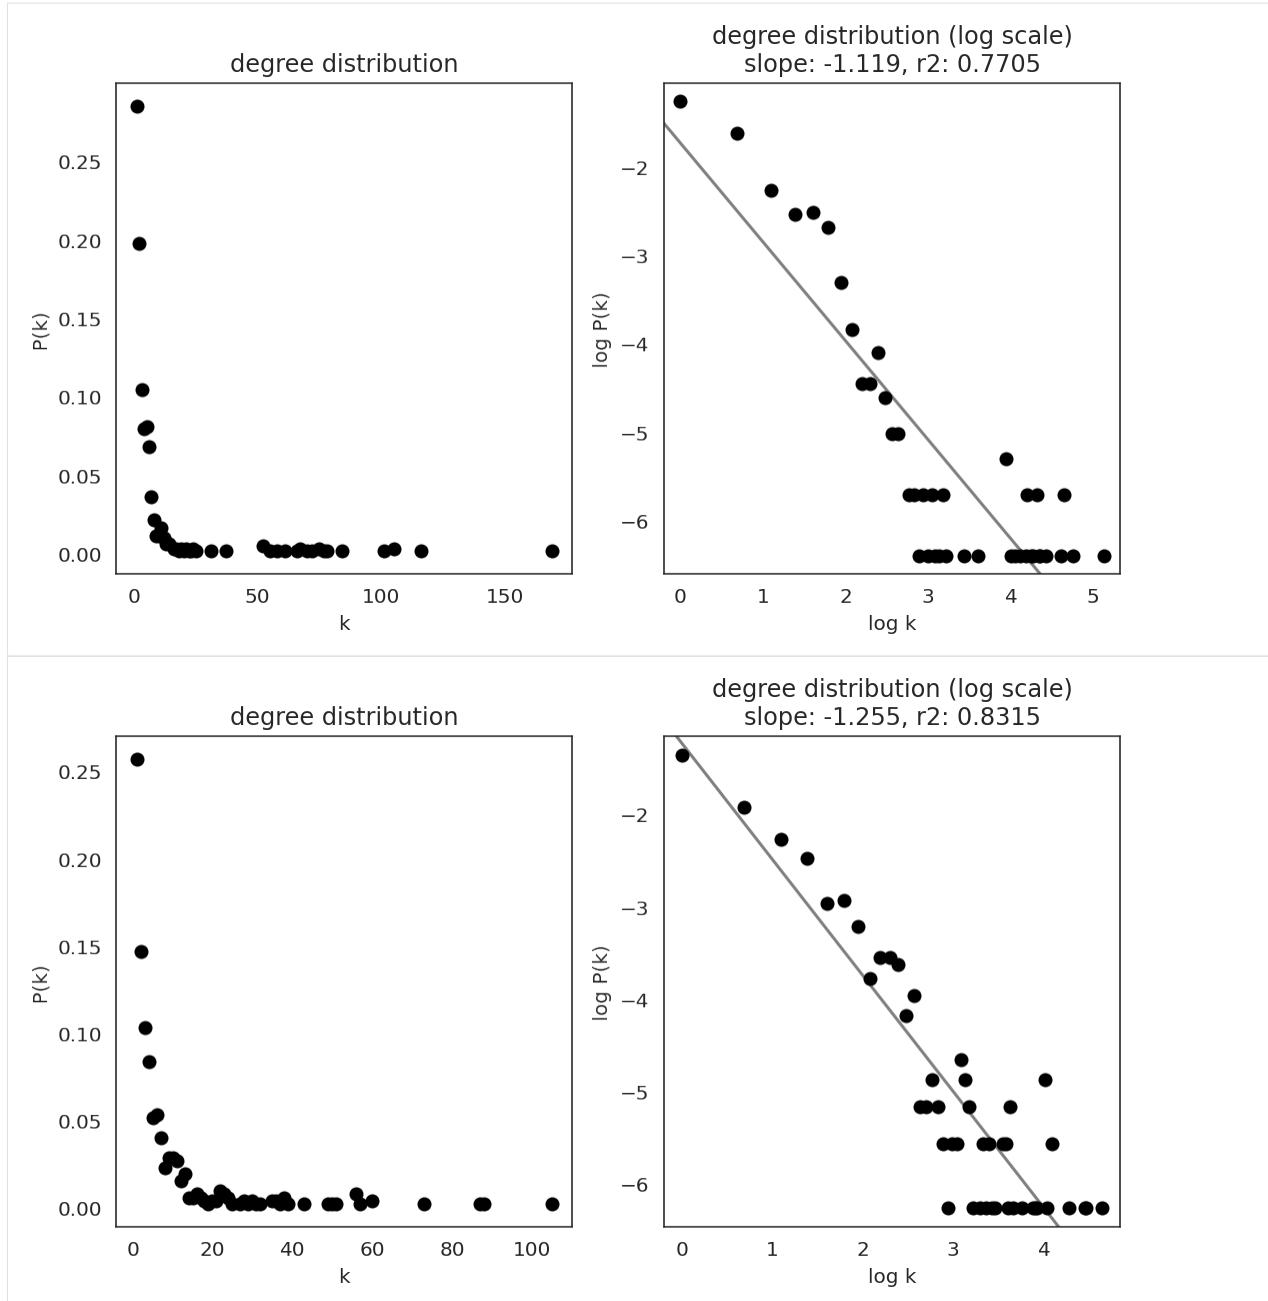

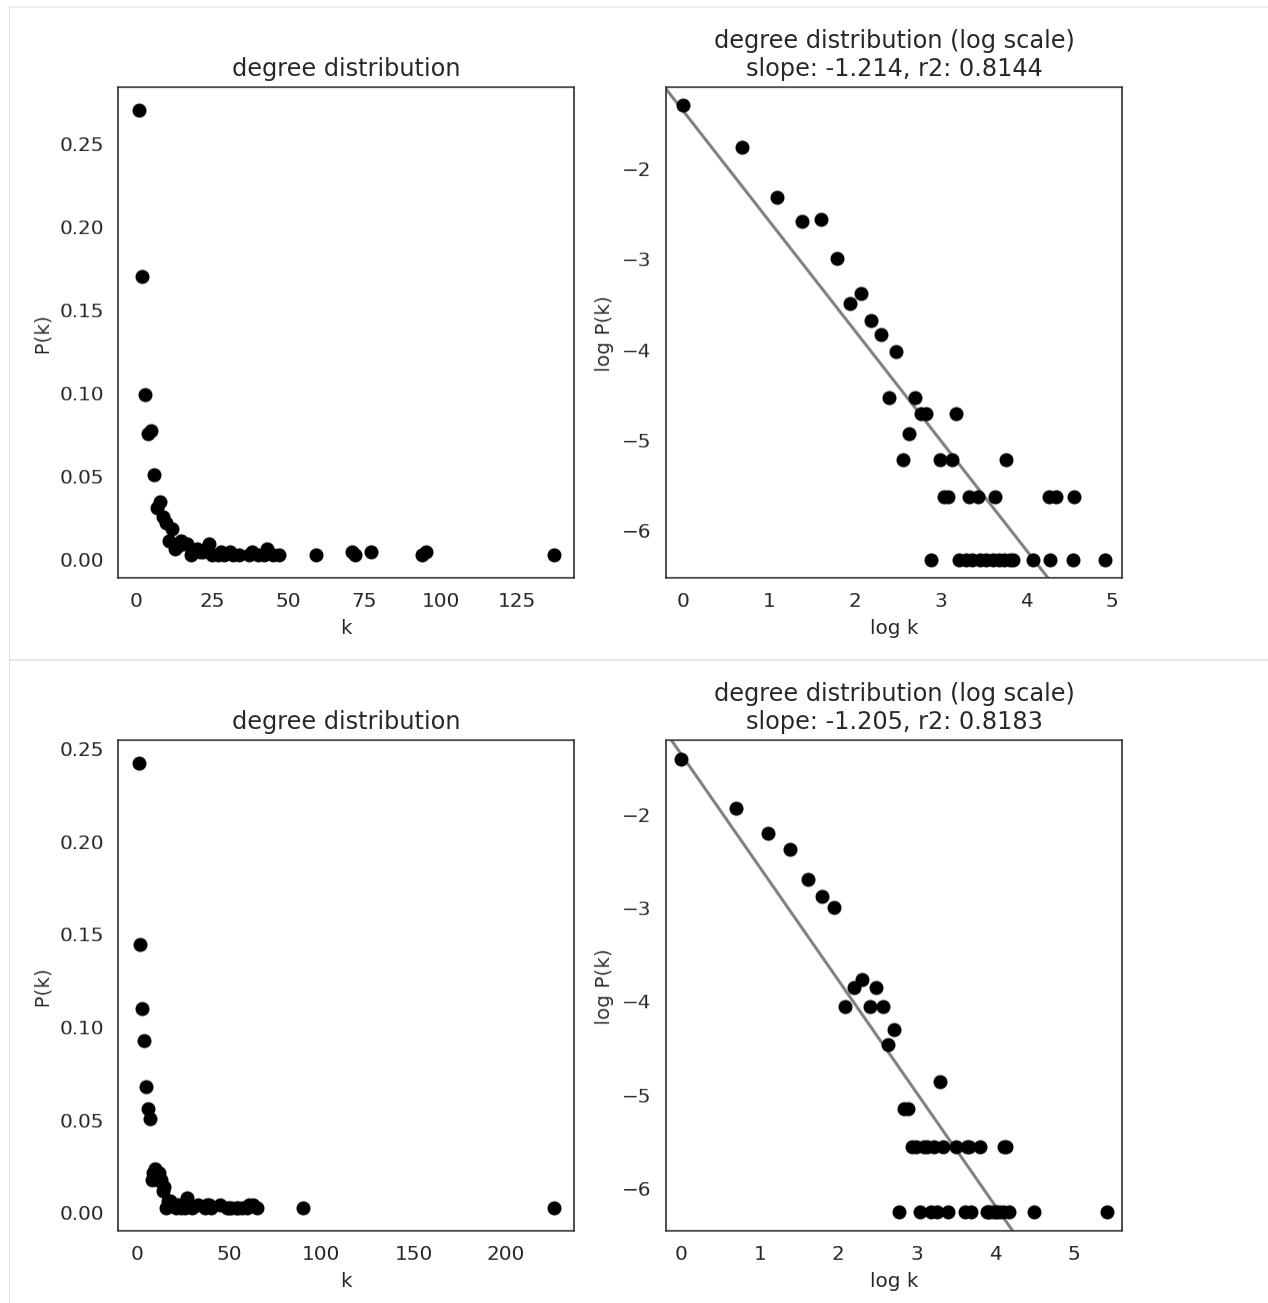

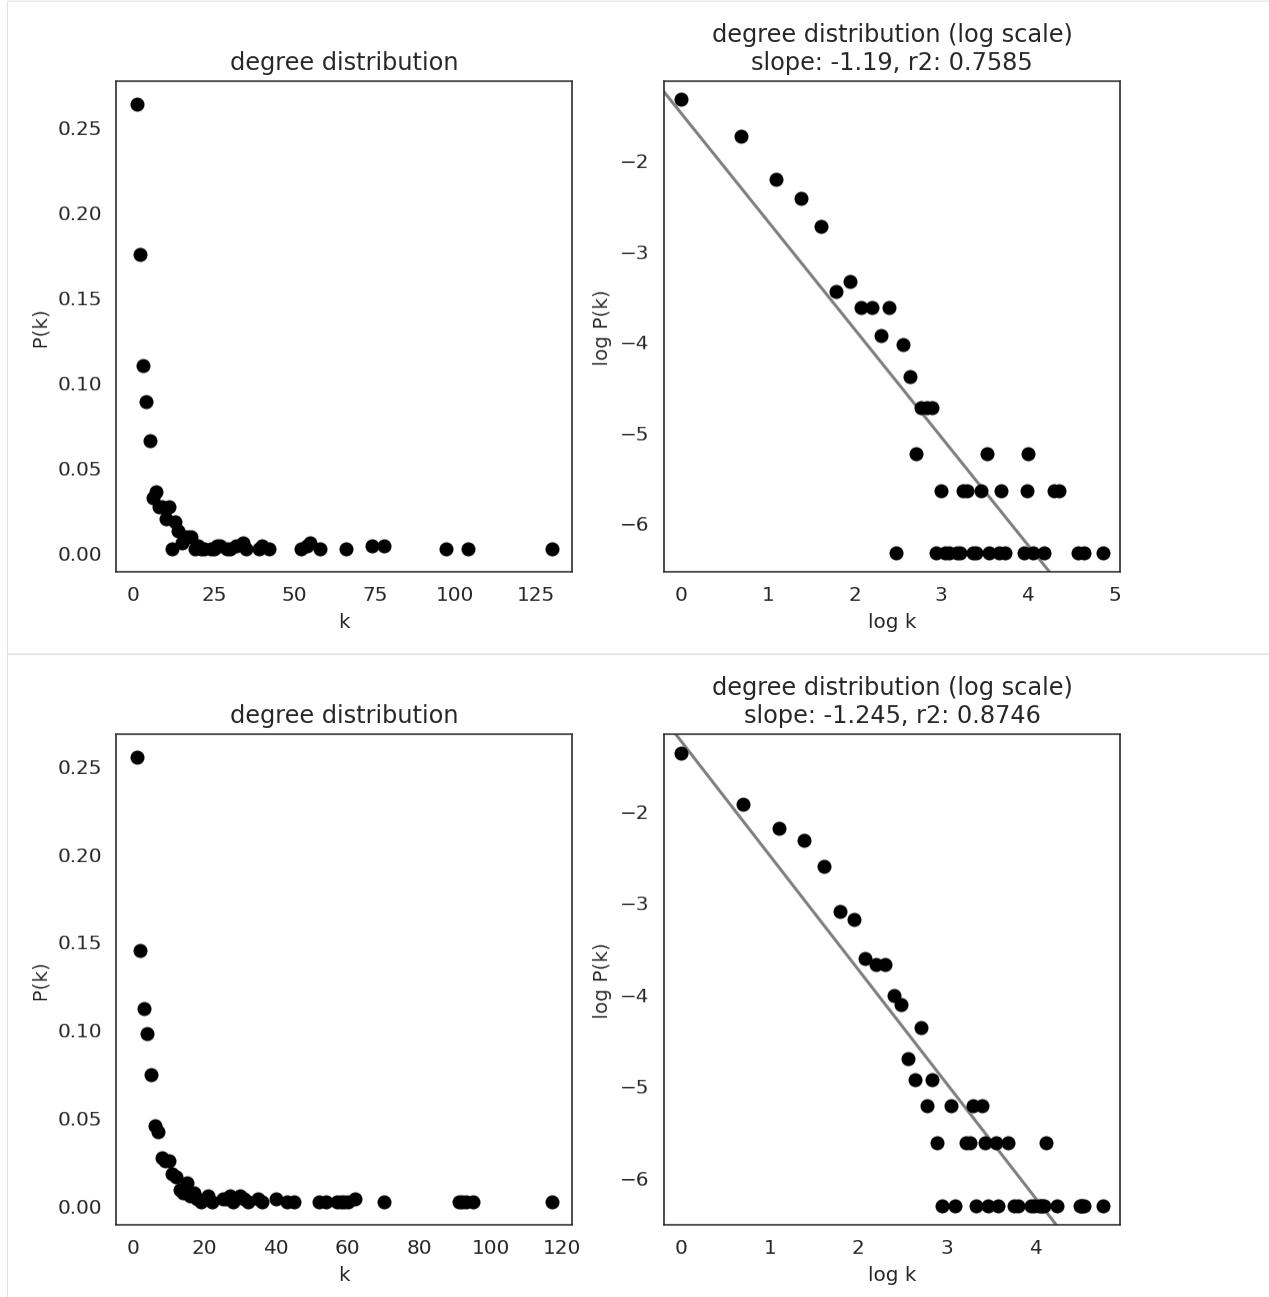

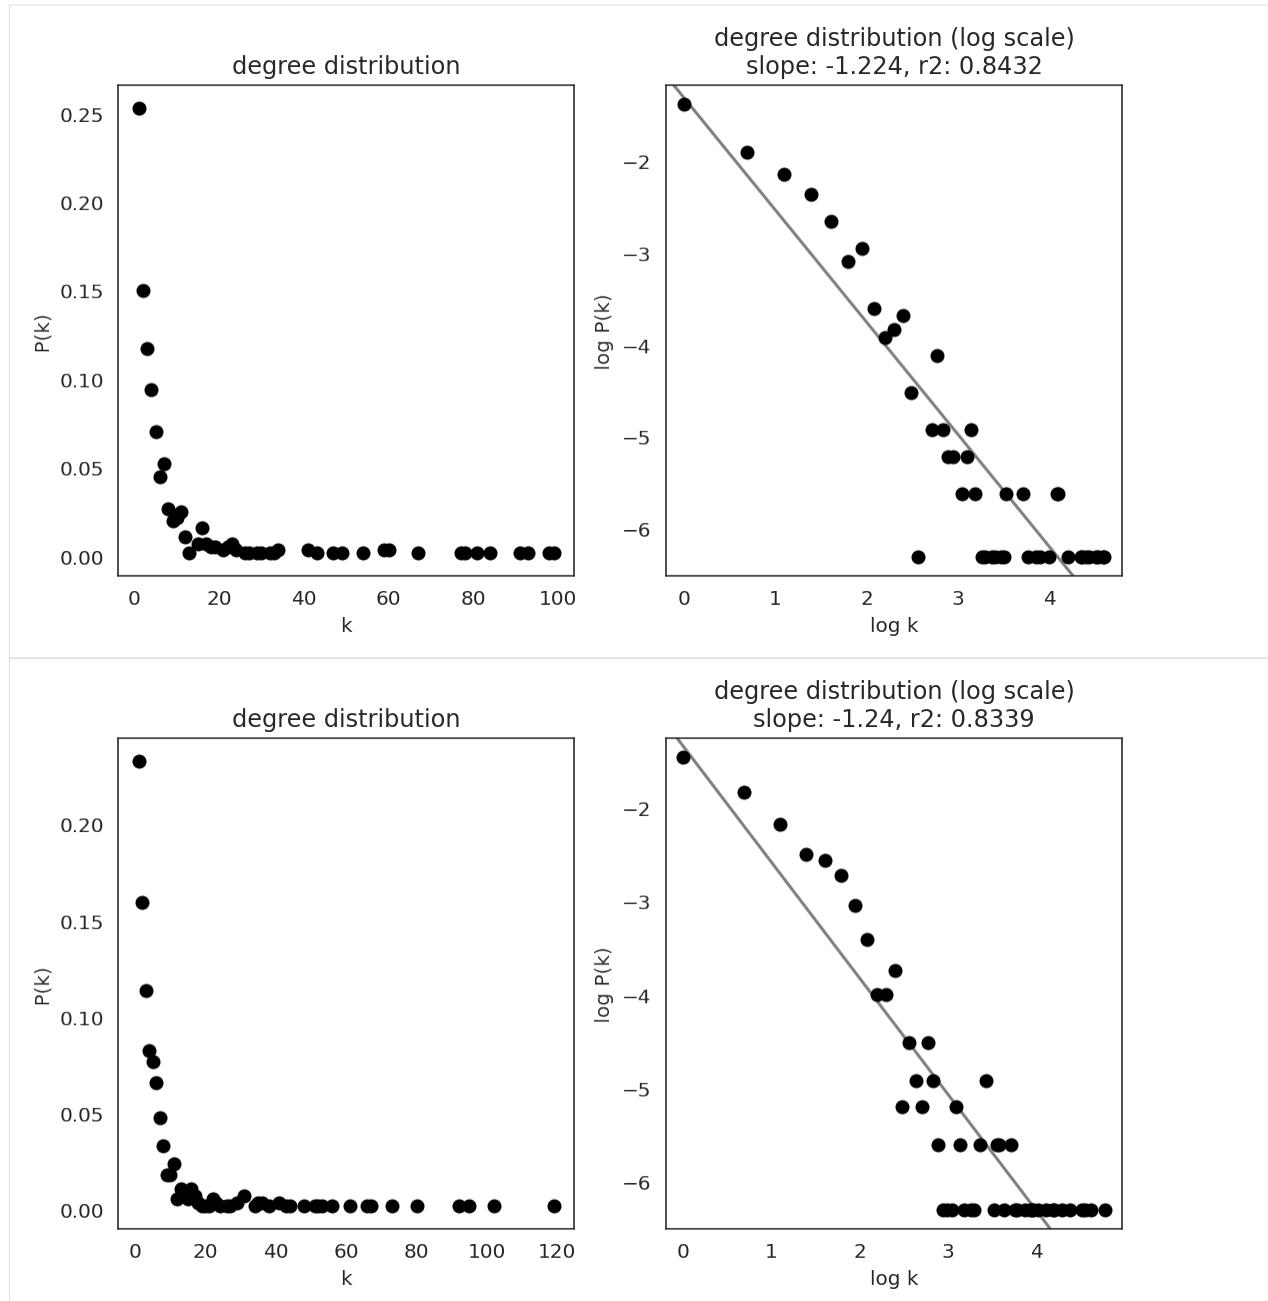

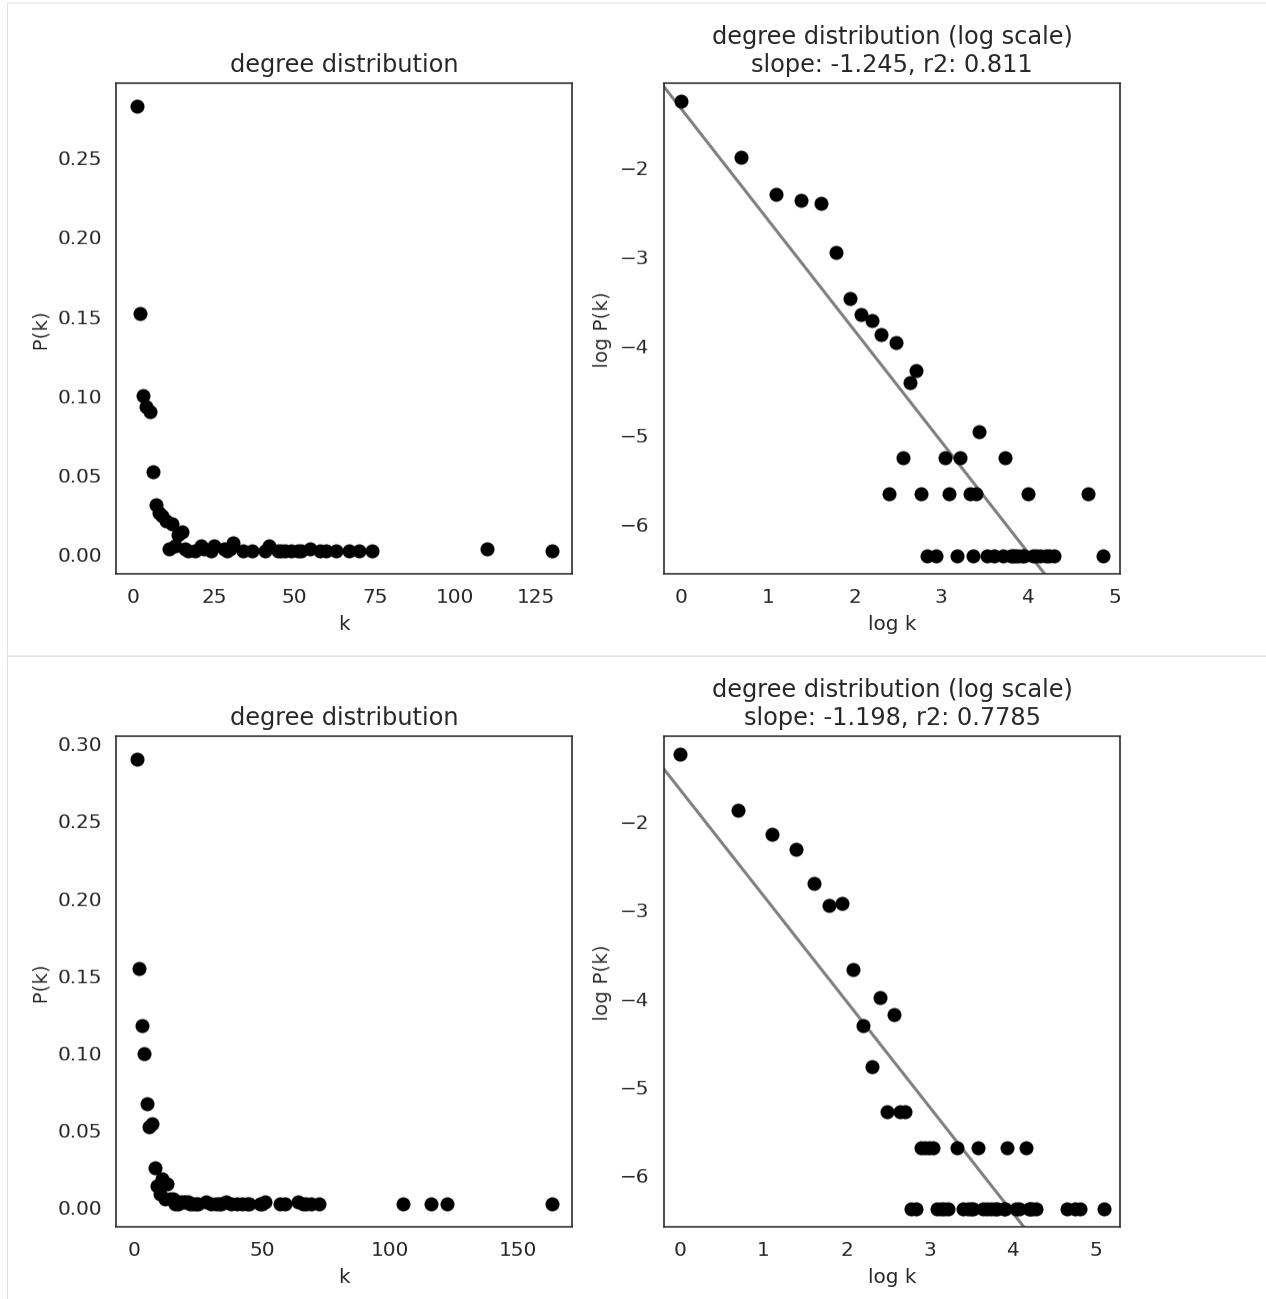

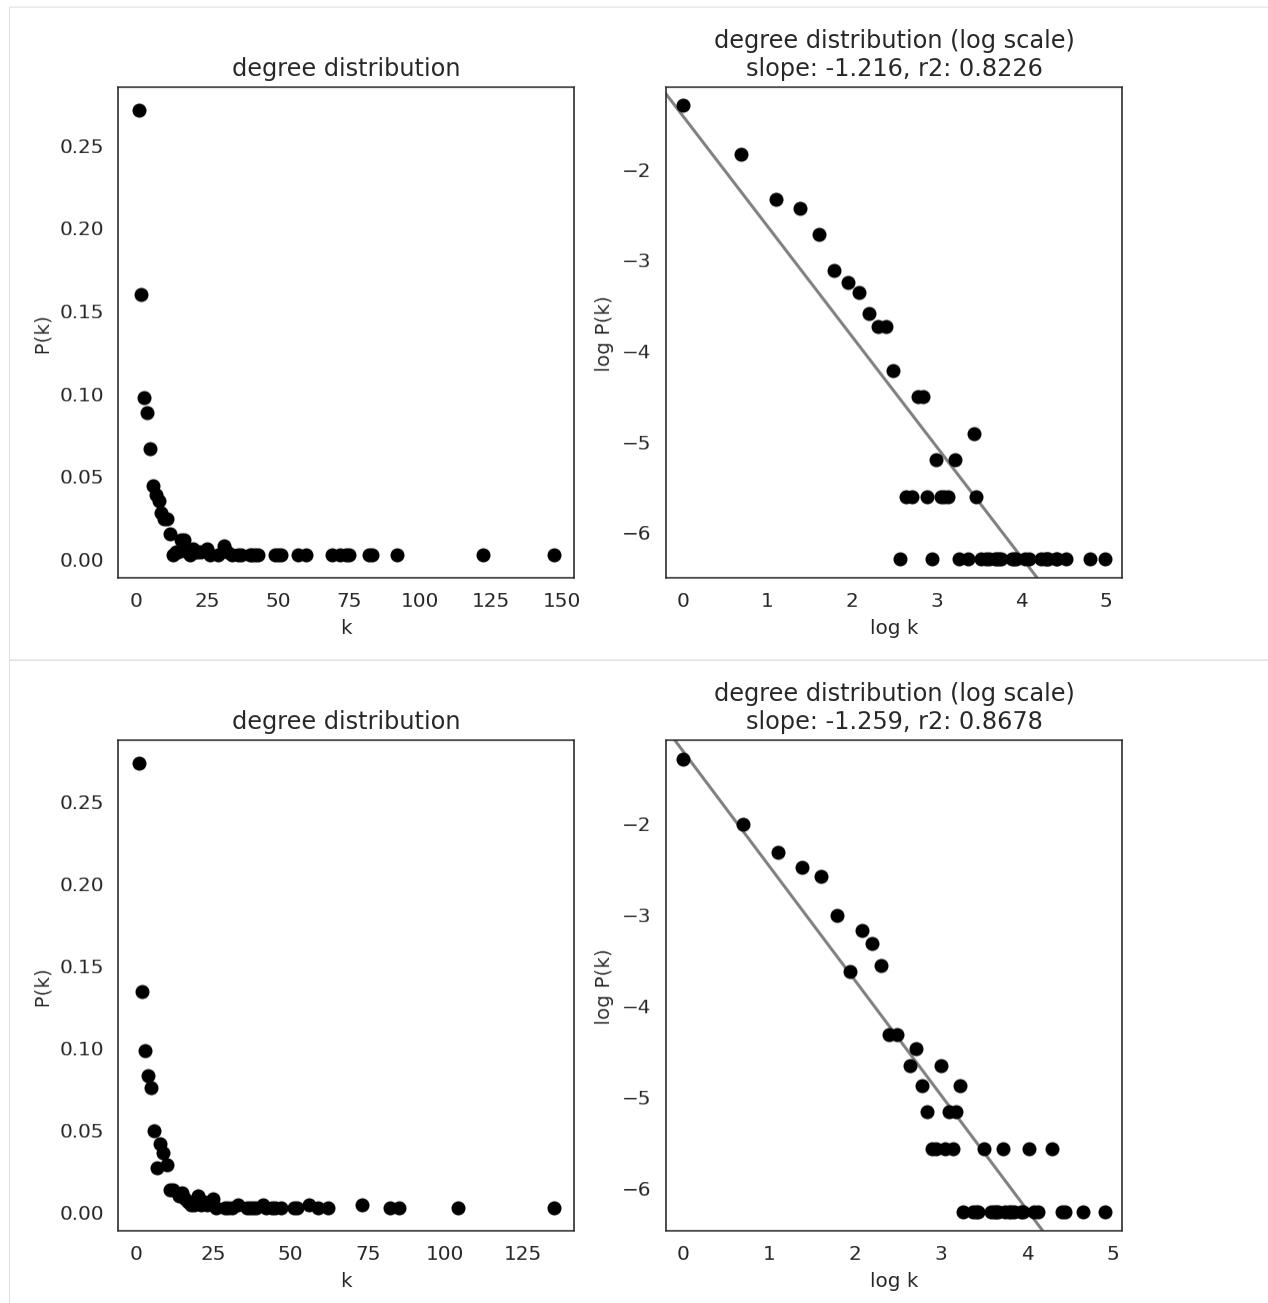

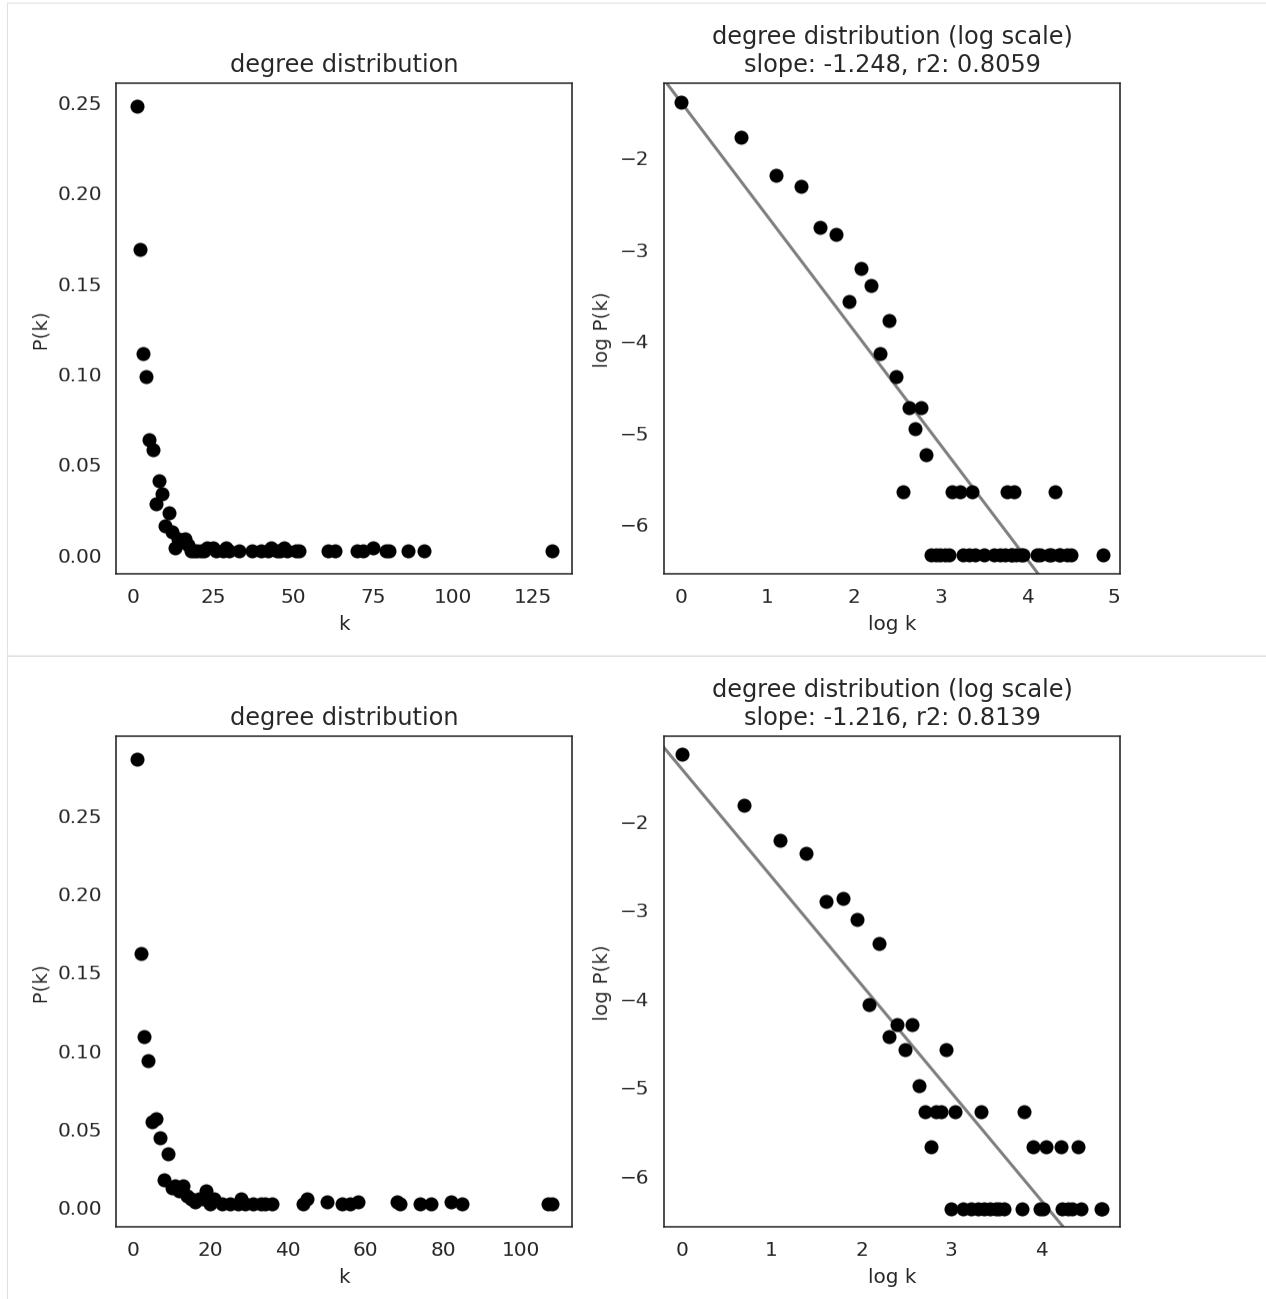

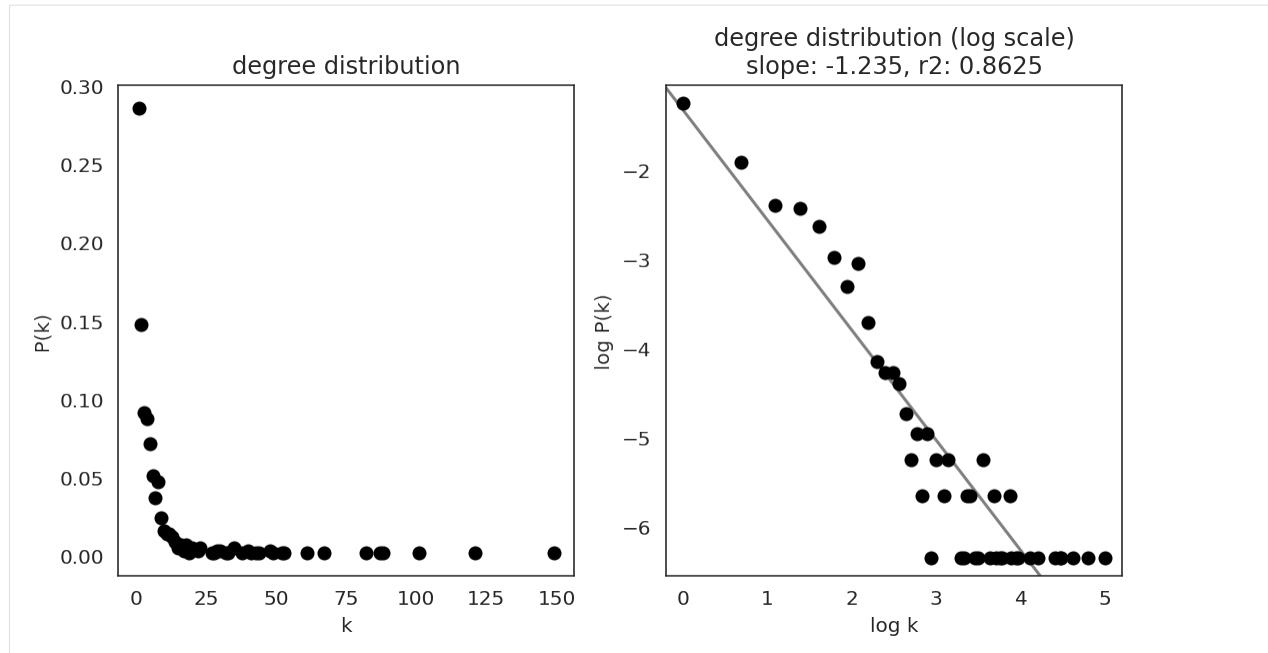

```
[50]: plt.rcParams["figure.figsize"] = [6, 4.5]
```

5.3. Calculate netowrk score

Next, we calculate several network score using some R libraries. Please make sure that R libraries are installed in your PC before running the command below.

```
[25]: # Calculate network scores. It takes several minutes.
links.get_score()

processing... batch 1/3
Ery_0: finished.
Ery_1: finished.
Ery_2: finished.
Ery_3: finished.
Ery_4: finished.
Ery_5: finished.
Ery_6: finished.
Ery_7: finished.
processing... batch 2/3
Ery_8: finished.
Ery_9: finished.
GMP_0: finished.
GMP_1: finished.
GMP_1_0: finished.
Gran_0: finished.
Gran_1: finished.
Gran_2: finished.
processing... batch 3/3
MEP_0: finished.
Mk_0: finished.
Mo_0: finished.
Mo_1: finished.
```

The score is stored as a attribute called “merged_score”, and the score will also be saved in a folder in your computer.

```
[51]: links.merged_score.head()

[51]:      degree_all  degree_in  degree_out  clustering_coefficient \

```

6.4. Save

Save processed GRN. We use this file in the next notebook; “in silico perturbation with GRNs”.

```
[52]: # Save Links object.
links.to_hdf5(file_path="links.celloracle.links")
```

```
[6]: # You can load files with the following command.
links = co.load_hdf5(file_path="links.celloracle.links")
```

7. Network analysis; Network score for each gene

The Links class has many functions to visualize network score. See the documentation for the details of the functions.

7.1. Network score in each cluster

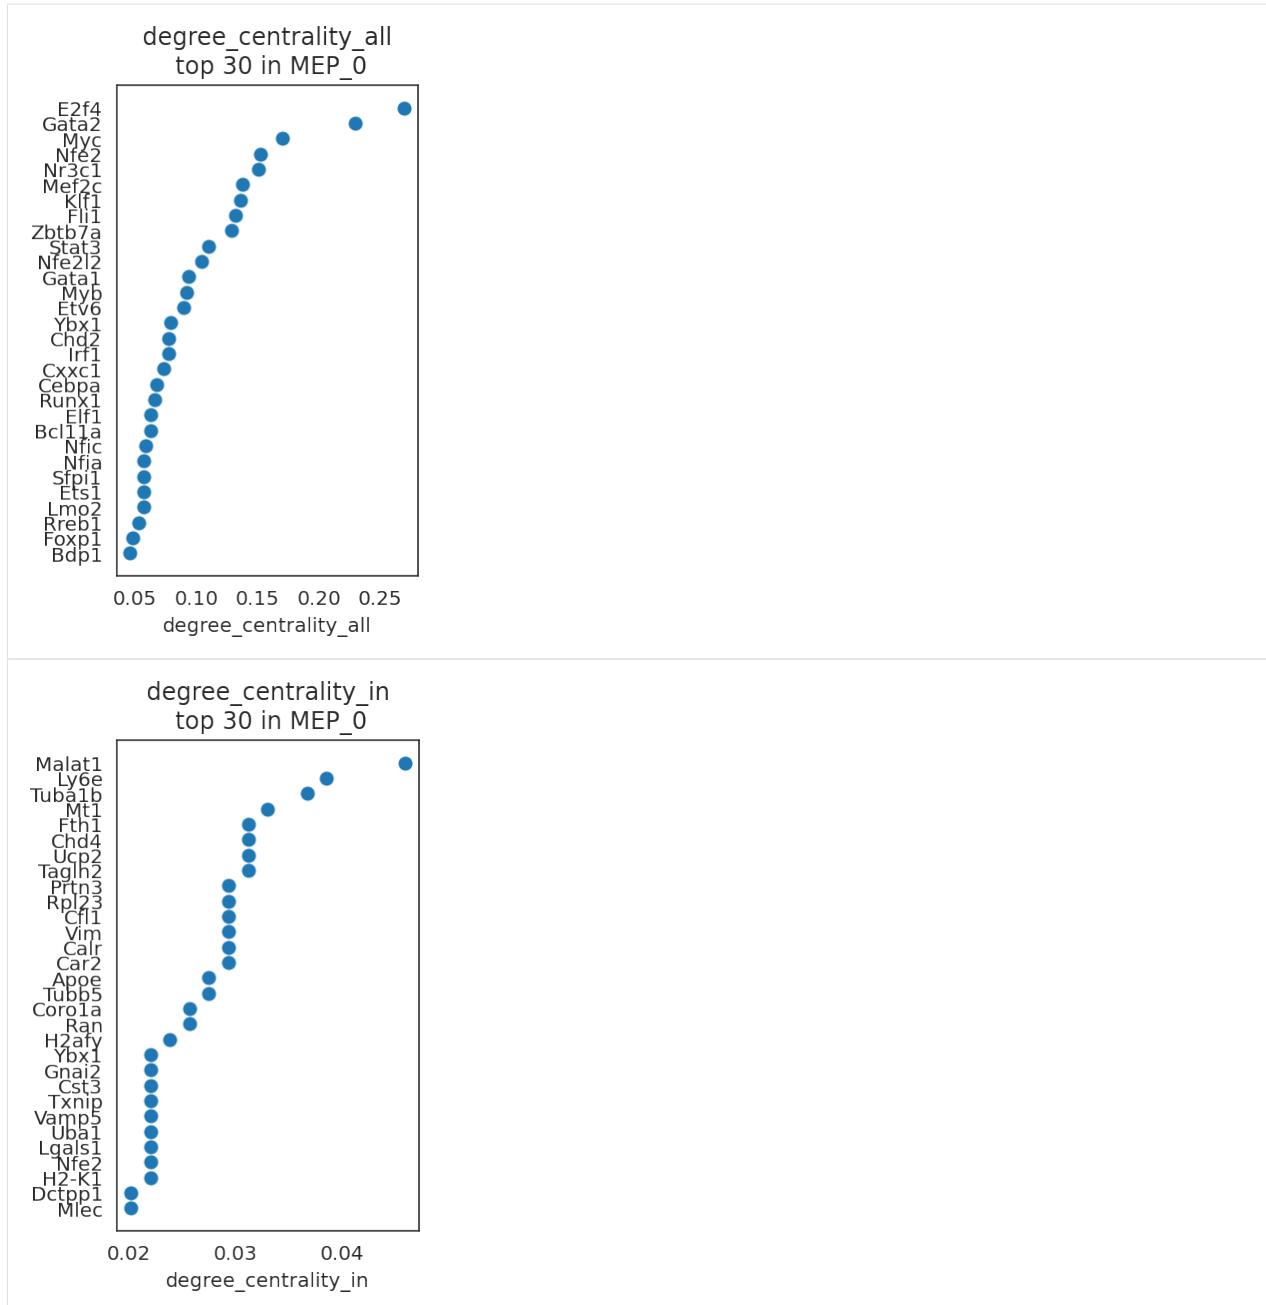

We have calculated several network scores using different centrality metrics. We can use the centrality score to identify key regulatory genes because centrality is one of the important indicators of network structure (<https://en.wikipedia.org/wiki/Centrality>).

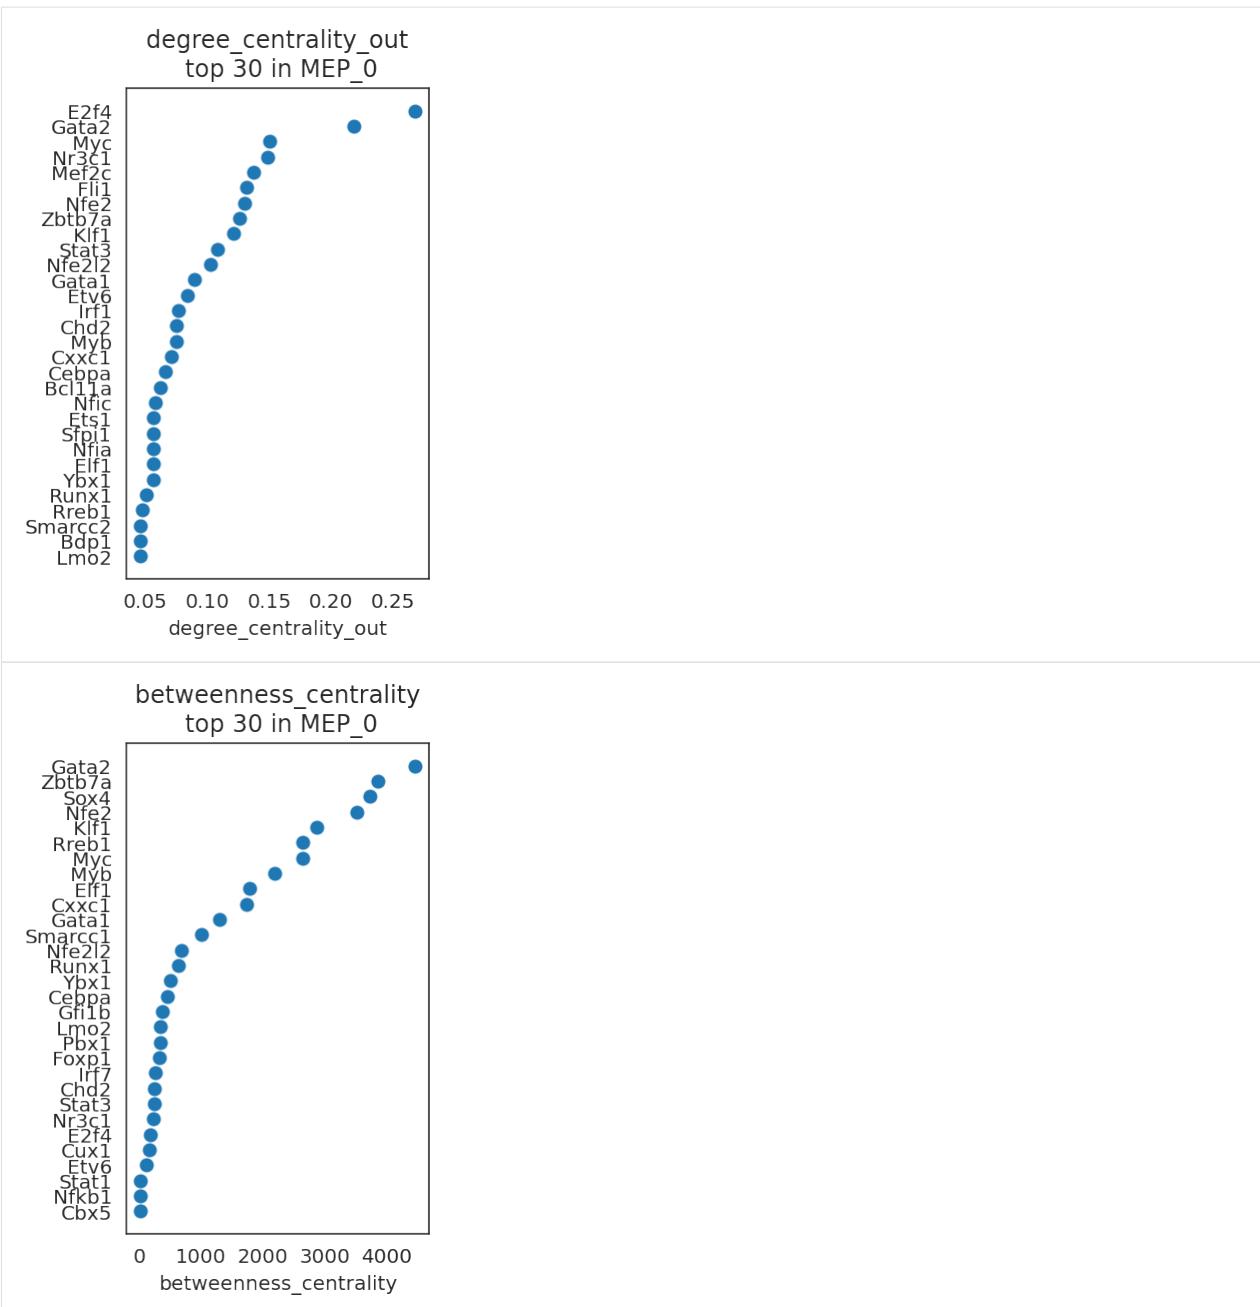

Let’s visualize genes with high network centrality.

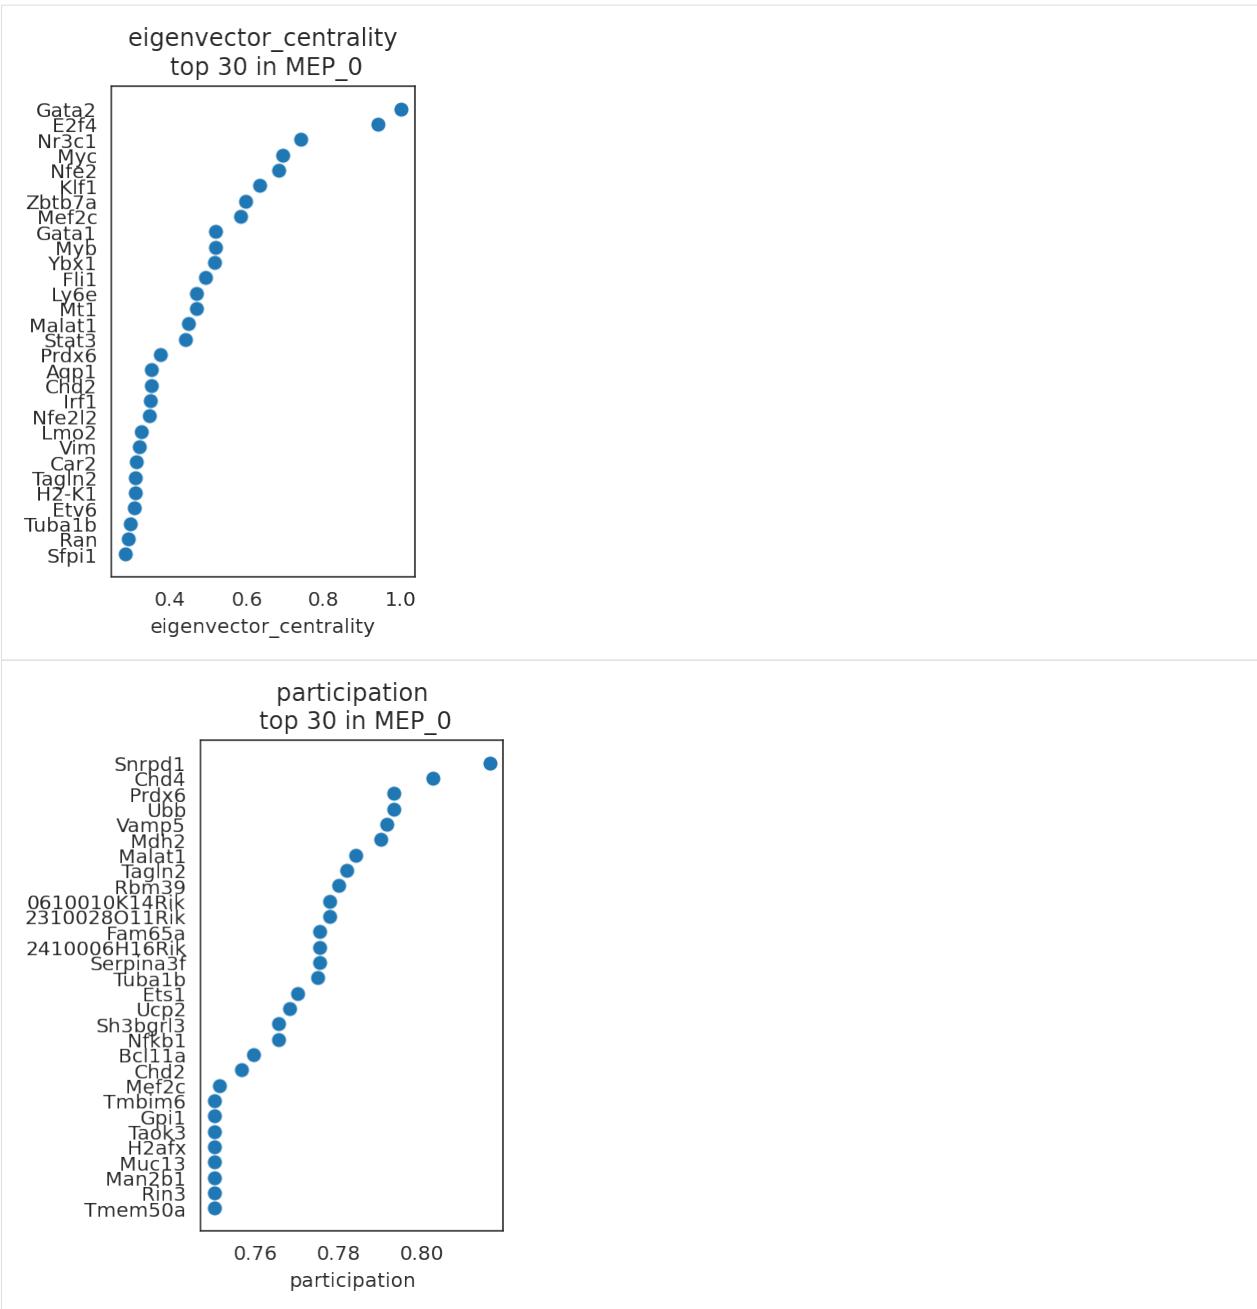

```
[53]: # Check cluster name
links.cluster
```

```
[53]: ['Ery_0',
'Ery_1',
'Ery_2',
'Ery_3',
'Ery_4',
'Ery_5',
'Ery_6',
'Ery_7',
'Ery_8',
'Ery_9',
'GMP_0',
'GMP_1',
'GMP_2',
'GMP1_0',
'GMP1_1',
'Gran_0',
'Gran_1',
'Gran_2',
'Gran_3',
'MEP_0',
'Mk_0',
'Mo_0',
'Mo_1',
'Mo_2']
```

```
[54]: # Visualize top n-th genes that have high scores.
links.plot_scores_as_rank(cluster="MEP_0", n_gene=30, save=f"{save_folder}/ranked_
➥score")
```

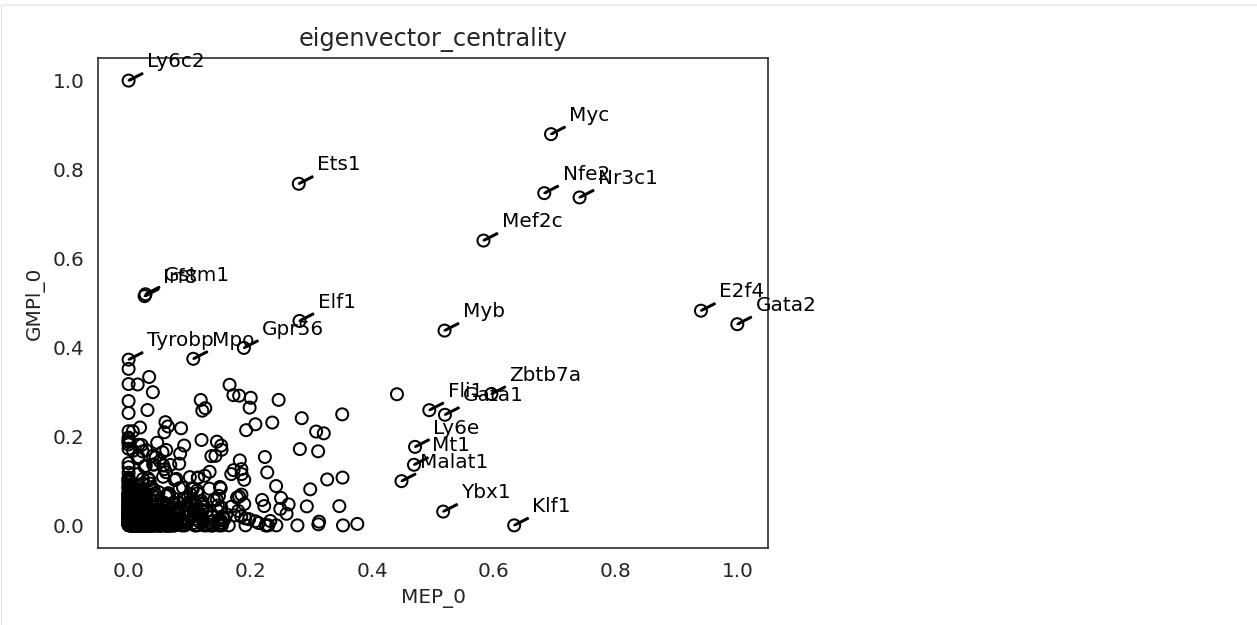

7.2. Network score comparison between two clusters

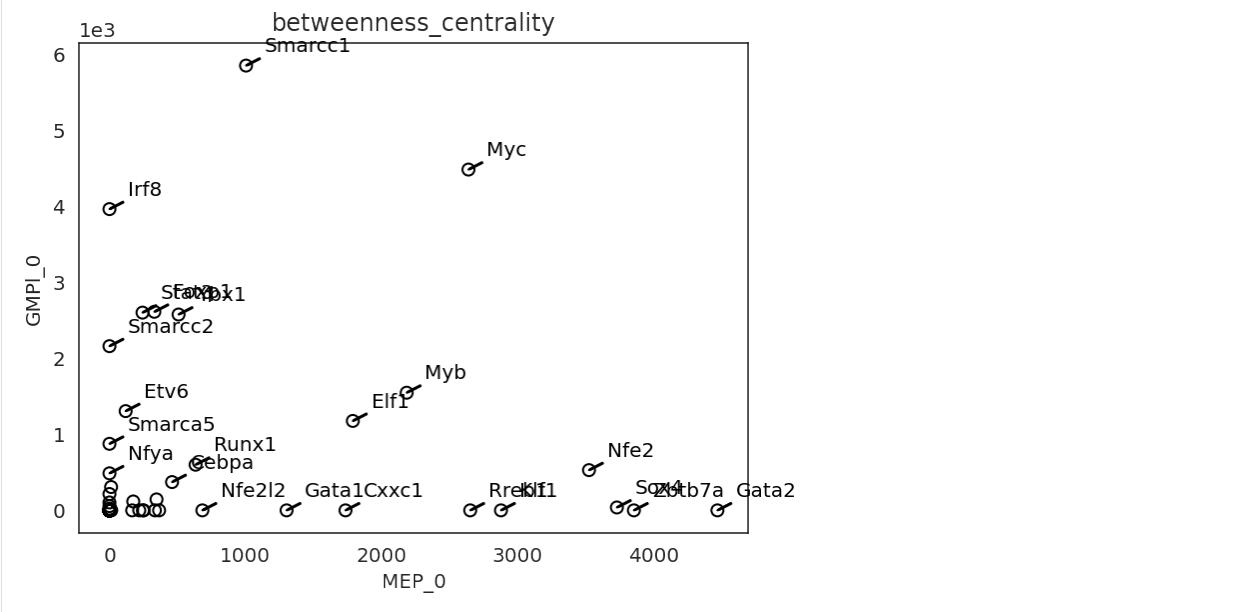

By comparing network scores between two clusters, we can analyze differences in GRN structure.

```
[55]: plt.ticklabel_format(style='sci',axis='y',scilimits=(0,0))
links.plot_score_comparison_2D(value="eigenvector_centrality",
                               cluster1="MEP_0", cluster2="GMP1_0",
                               percentile=98, save=f"{save_folder}/score_comparison")
```

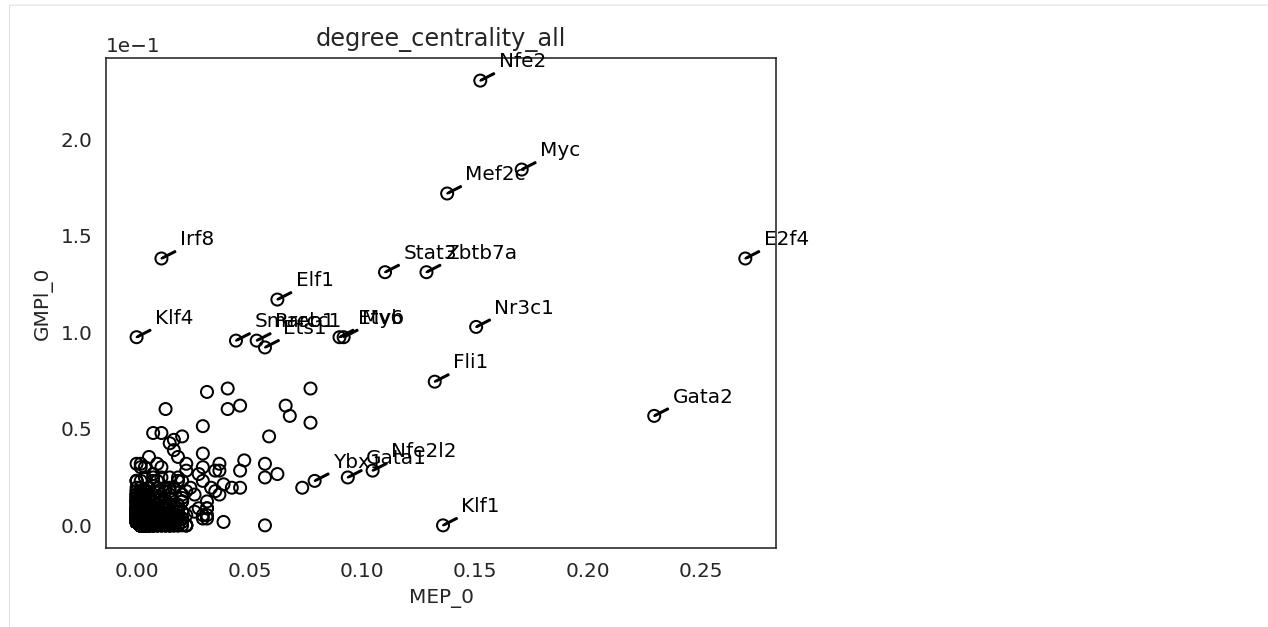

[56]:

```
plt.ticklabel_format(style='sci', axis='y', scilimits=(0,0))
links.plot_score_comparison_2D(value="betweenness_centrality",
                                cluster1="MEP_0", cluster2="GMP1_0",
                                percentile=98, save=f"{save_folder}/score_comparison")
```

[57]:

```
plt.ticklabel_format(style='sci', axis='y', scilimits=(0,0))
links.plot_score_comparison_2D(value="degree_centrality_all",
                                cluster1="MEP_0", cluster2="GMP1_0",
                                percentile=98, save=f"{save_folder}/score_comparison")
```

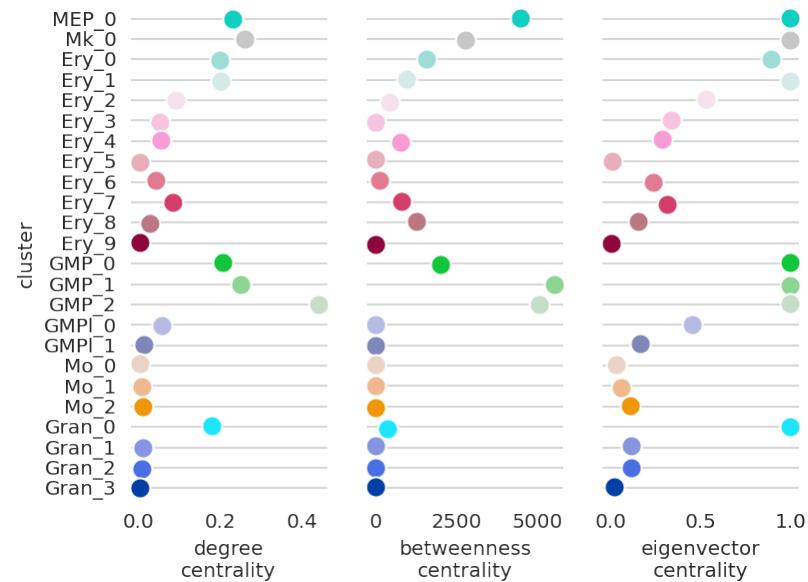

7.3. Network score dynamics

In the following session, we focus on how a gene's network score changes during the differentiation.

Using Gata2, we will demonstrate how you can visualize networks scores for a single gene.

Gata2 is known to play an essential role in the early MEP and GMP populations. .

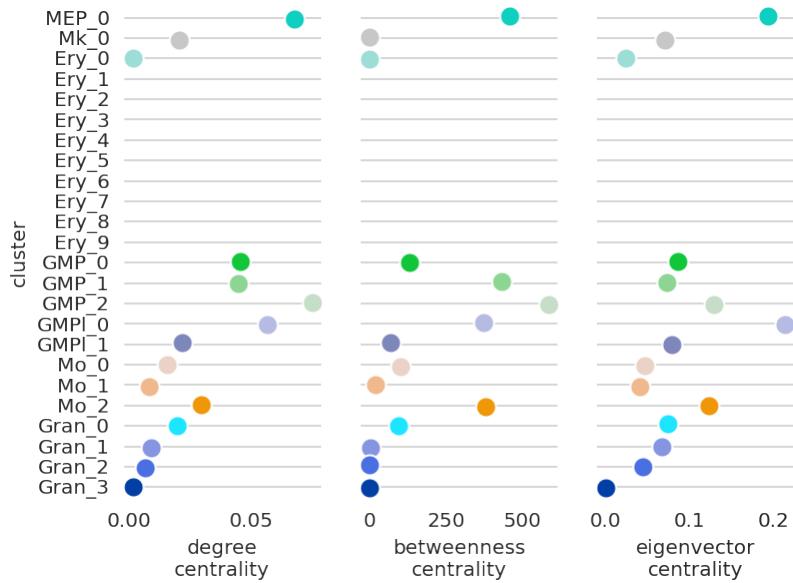

```
[58]: # Visualize Gata2 network score dynamics
links.plot_score_per_cluster(goi="Gata2", save=f"{save_folder}/network_score_per_gene/")
```

If a gene have no connections in a cluster, it is impossible to calculate network degree scores. Thus the scores will not be shown. For example, Cebpa have no connection in the erythroids clusters, and there is no degree scores for Cebpa

in these clusters as follows.

```
[59]: links.plot_score_per_cluster(goi="Cebpa")
```

You can check filtered network edge as follows.

```
[62]: cluster_name = "Ery_1"
filtered_links_df = links.filtered_links[cluster_name]
filtered_links_df.head()
```

	source	target	coef_mean	coef_abs	p	-logp
5480	Gata2	Apoe	0.100094	0.100094	6.274381e-16	15.202429
5496	Zfhx3	Apoe	0.098389	0.098389	1.749953e-13	12.756974
68791	Hnf4a	Top2a	0.098258	0.098258	7.209973e-10	9.142066
48857	E2f4	Phf10	0.095547	0.095547	1.429657e-13	12.844768
5470	Nfatc3	Apoe	-0.095185	0.095185	2.385889e-14	13.622350

You can confirm that there is no Cebpa connection in Ery_0 cluster.

```
[63]: filtered_links_df[filtered_links_df.source == "Cebpa"]
```

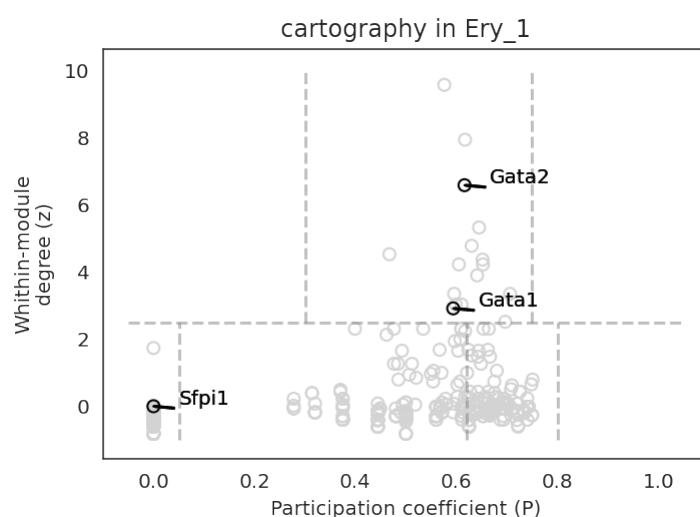

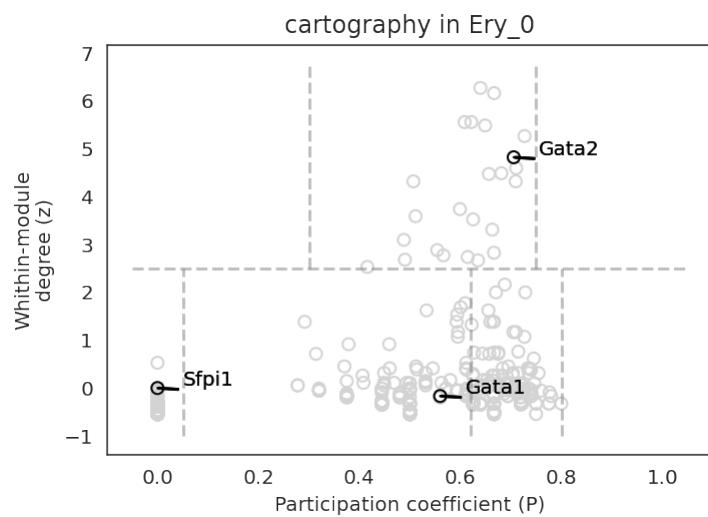

```
[63]: Empty DataFrame
Columns: [source, target, coef_mean, coef_abs, p, -logp]
Index: []
```

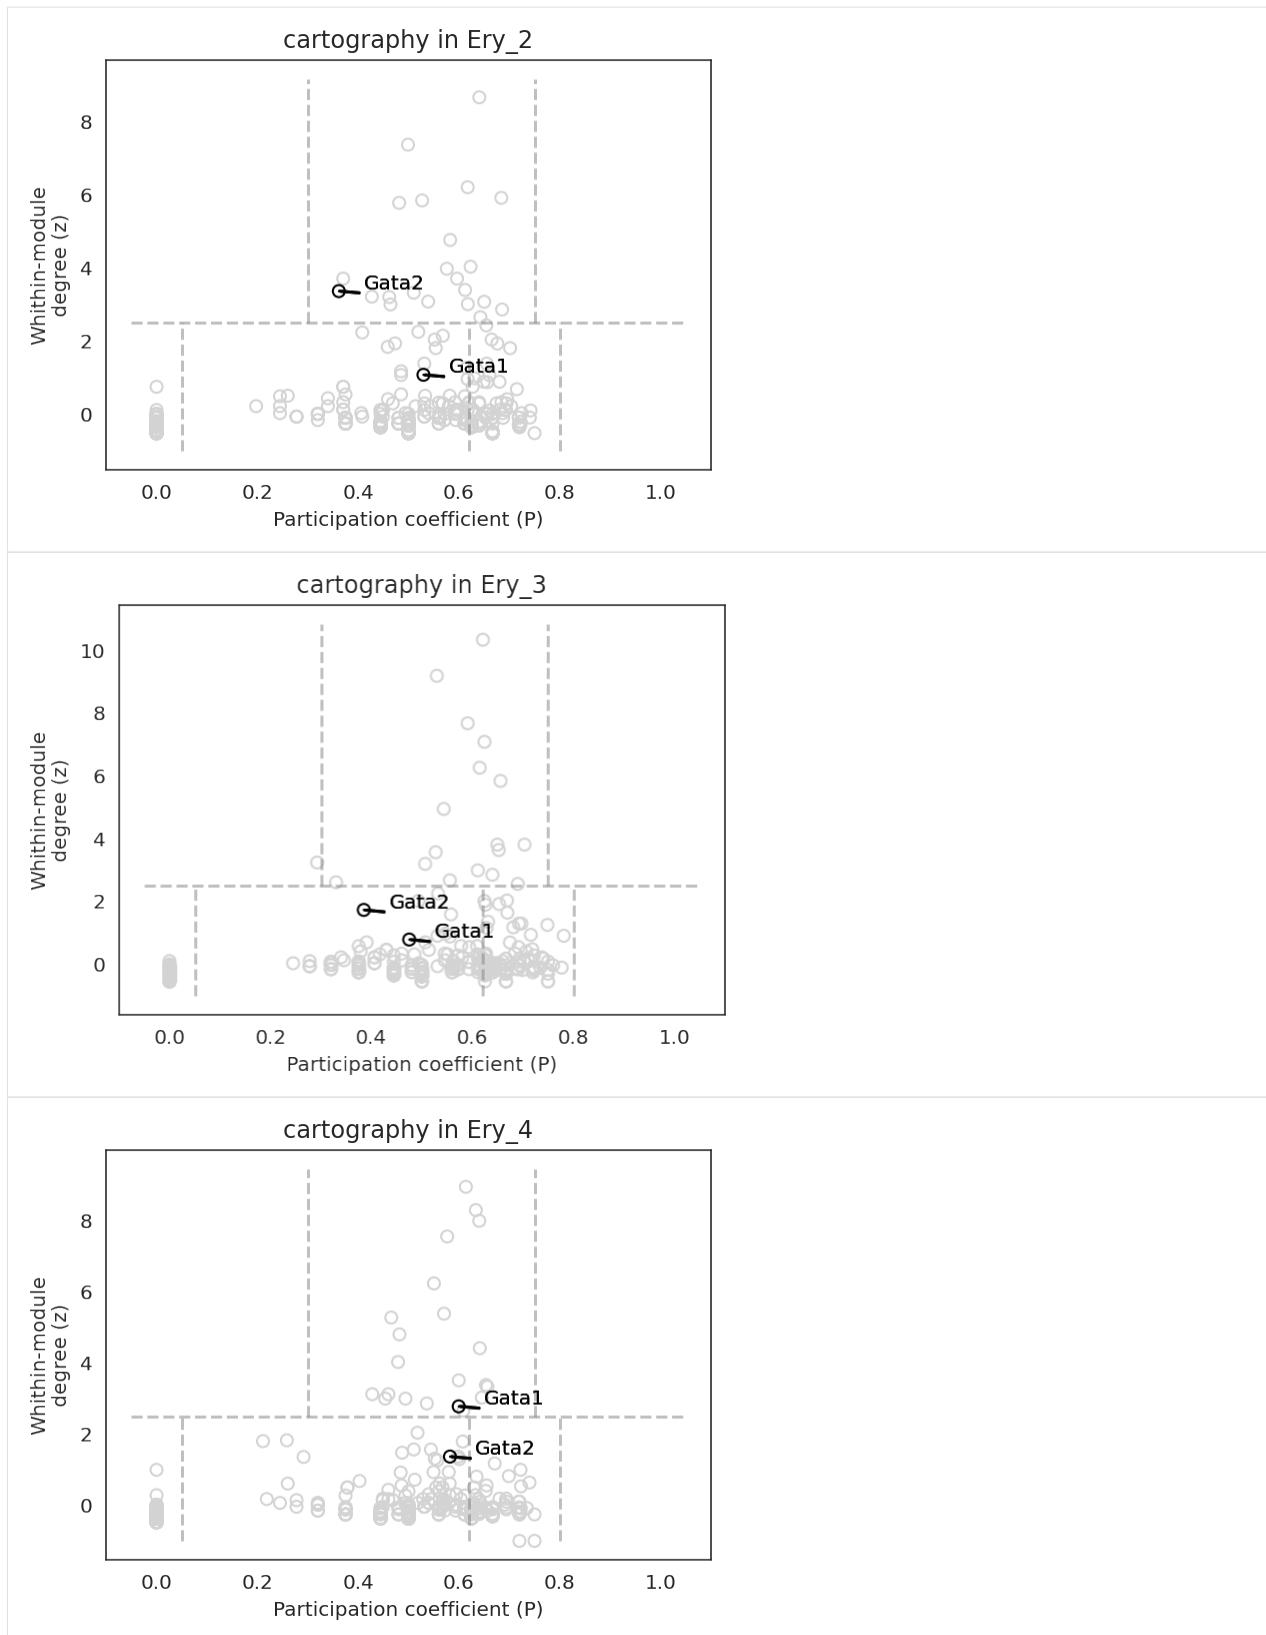

7.4. Gene cartography analysis

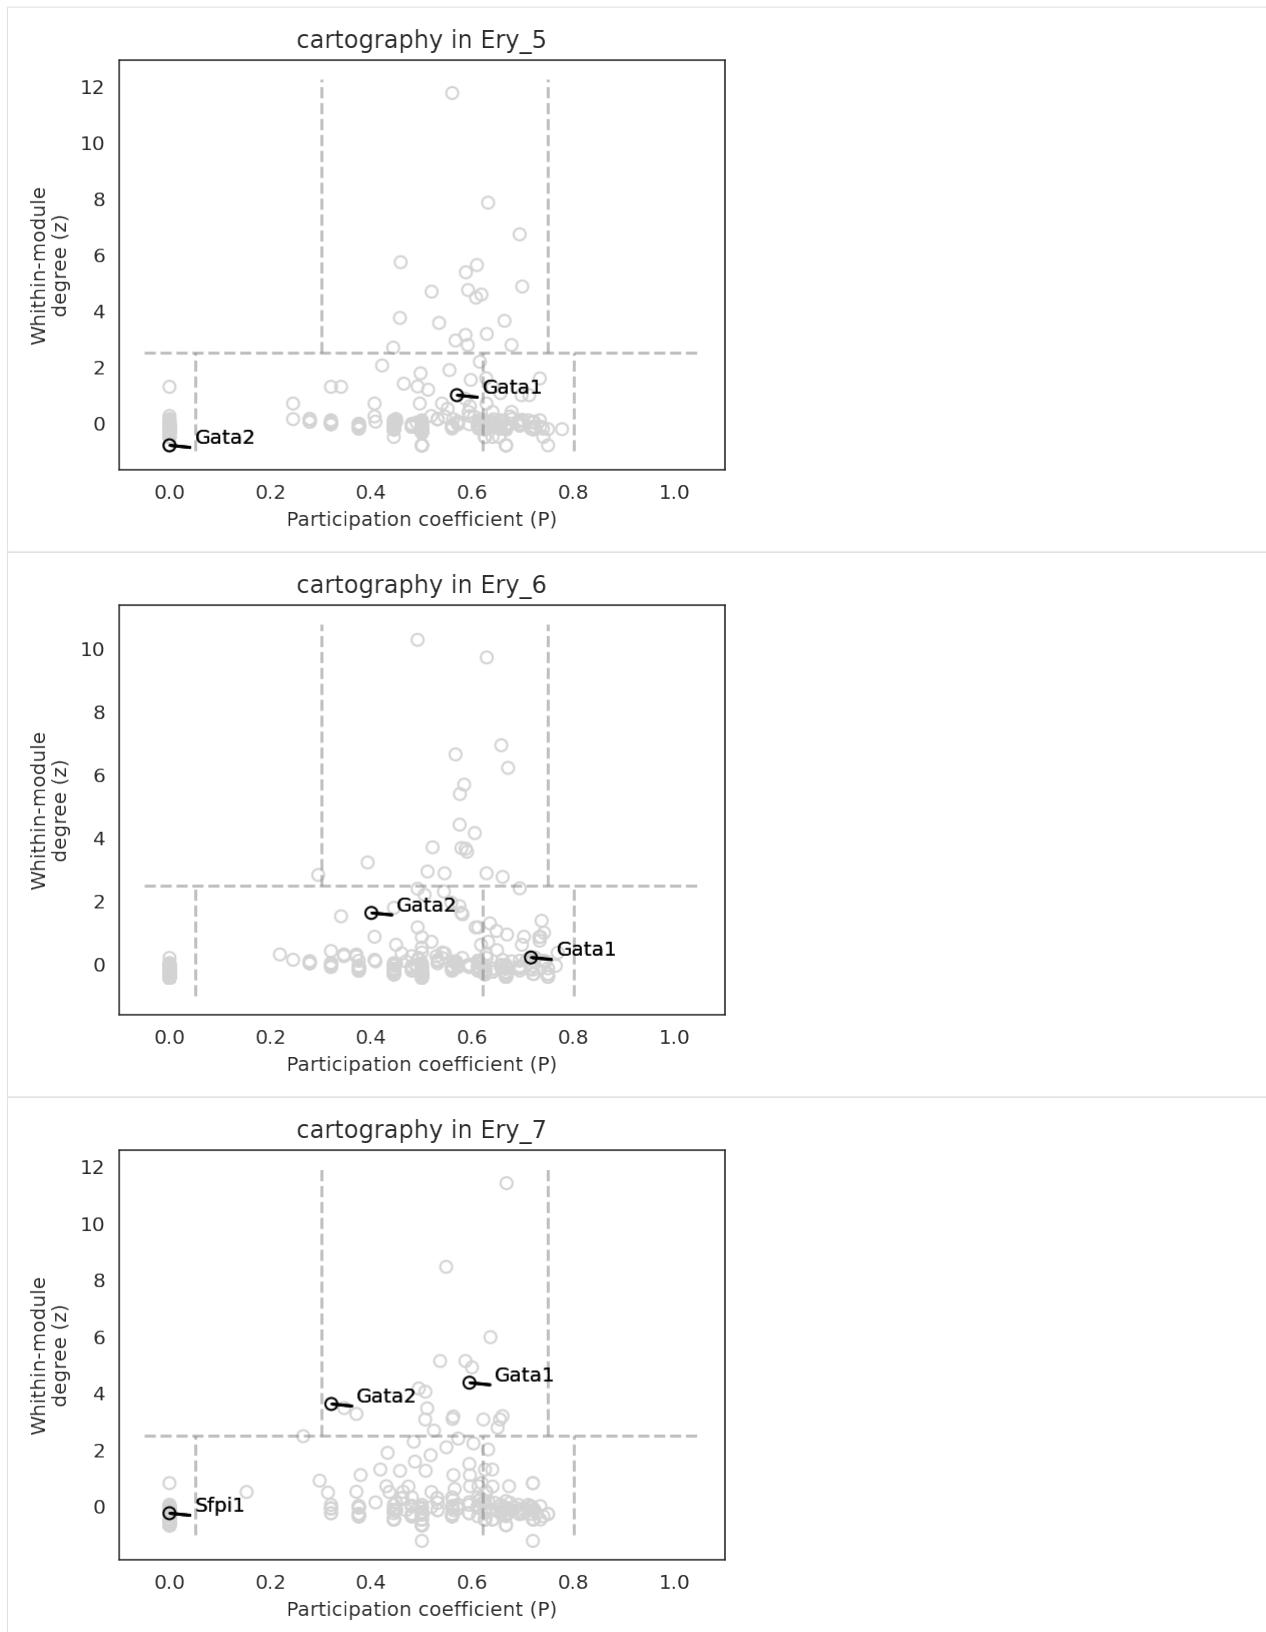

Gene cartography is a method for gene network analysis. The method classifies gene into several groups using the network module structure and connections. It provides us an insight about the role and regulatory mechanism for each gene. For more information on gene cartography, please refer to the following paper (<https://www.nature.com/articles/nature03288>).

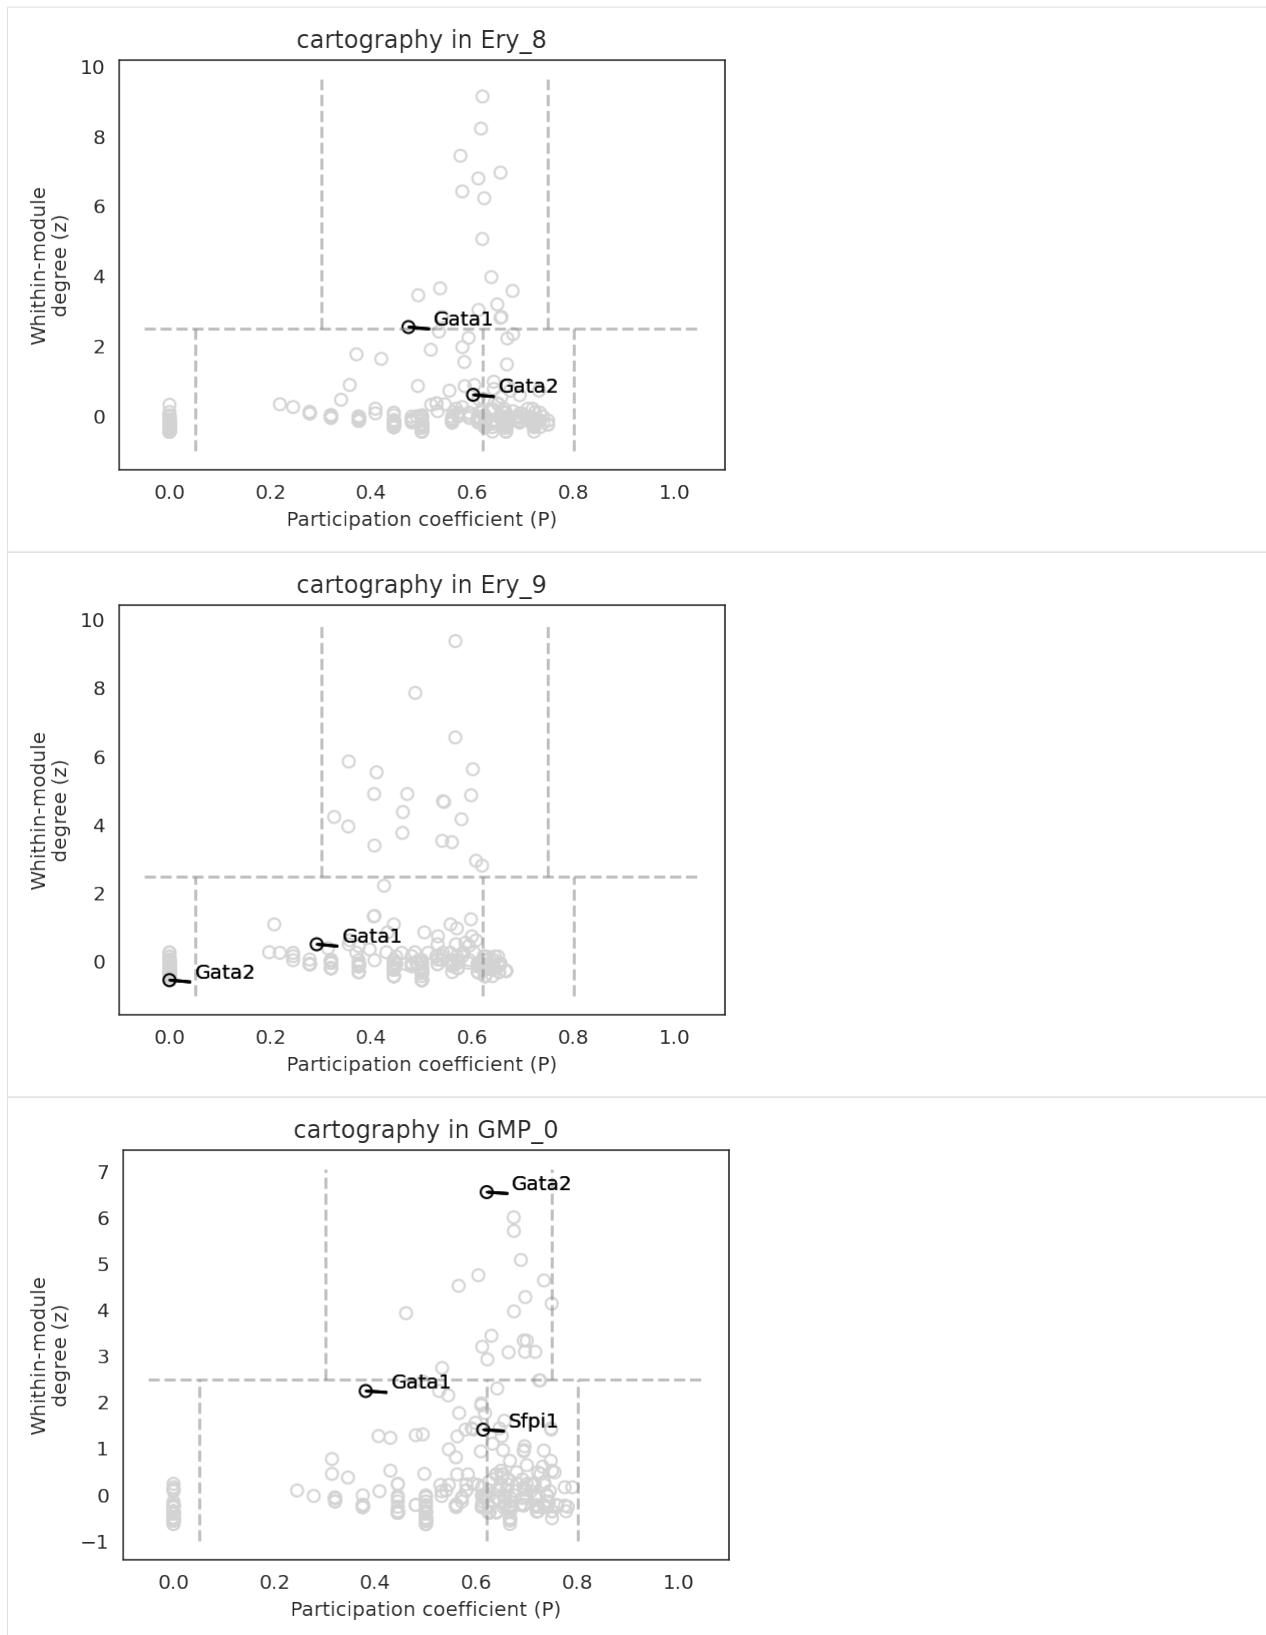

The gene cartography will be calculated for the GRN in each cluster. Thus we can know how the gene cartography change by comparing the the score between clusters.

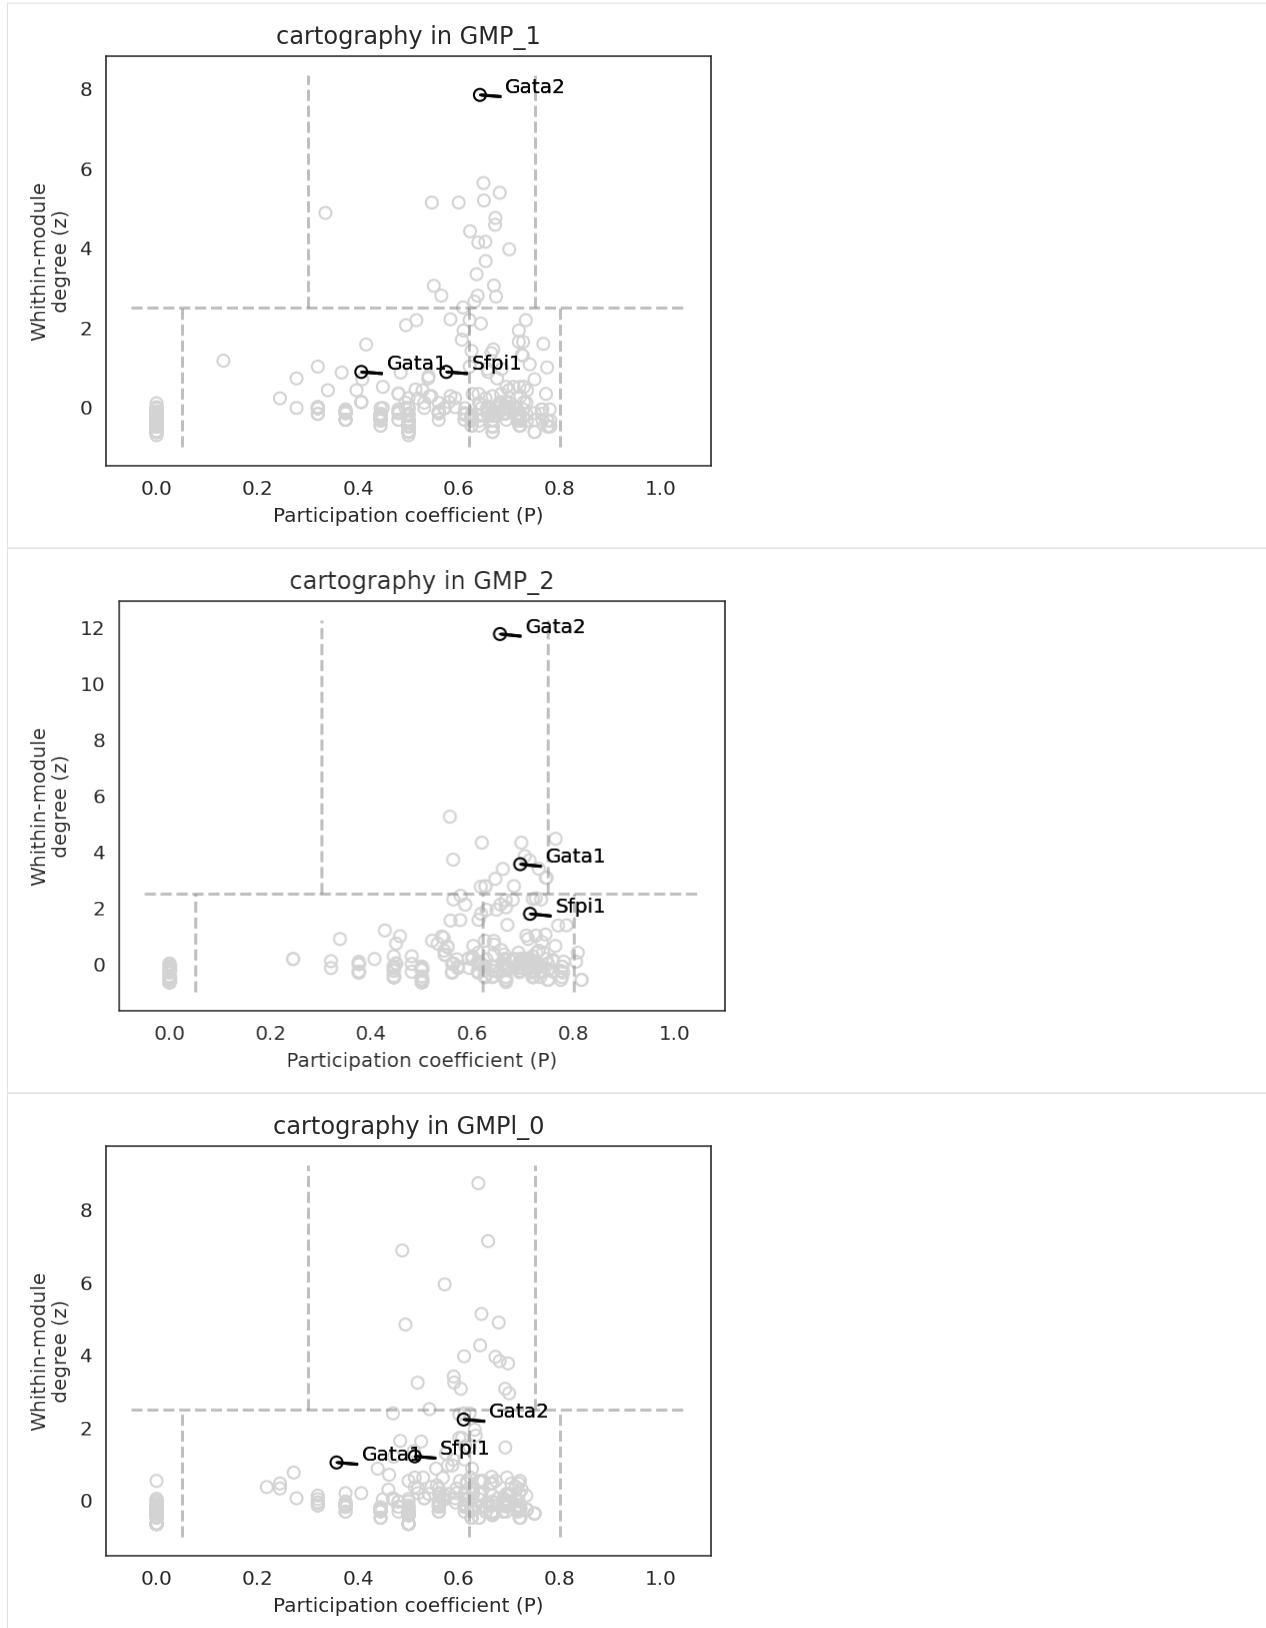

```
[64]: # Plot cartography as a scatter plot
links.plot_cartography_scatter_per_cluster(scatter=True,
                                             kde=False,
                                             gois=["Gata1", "Gata2", "Sfpi1"],
                                             auto_gene_annot=False,
                                             args_dot={"n_levels": 105},
                                             args_line={"c": "gray"}, save=
                                             ↪folder}/cartography")
```

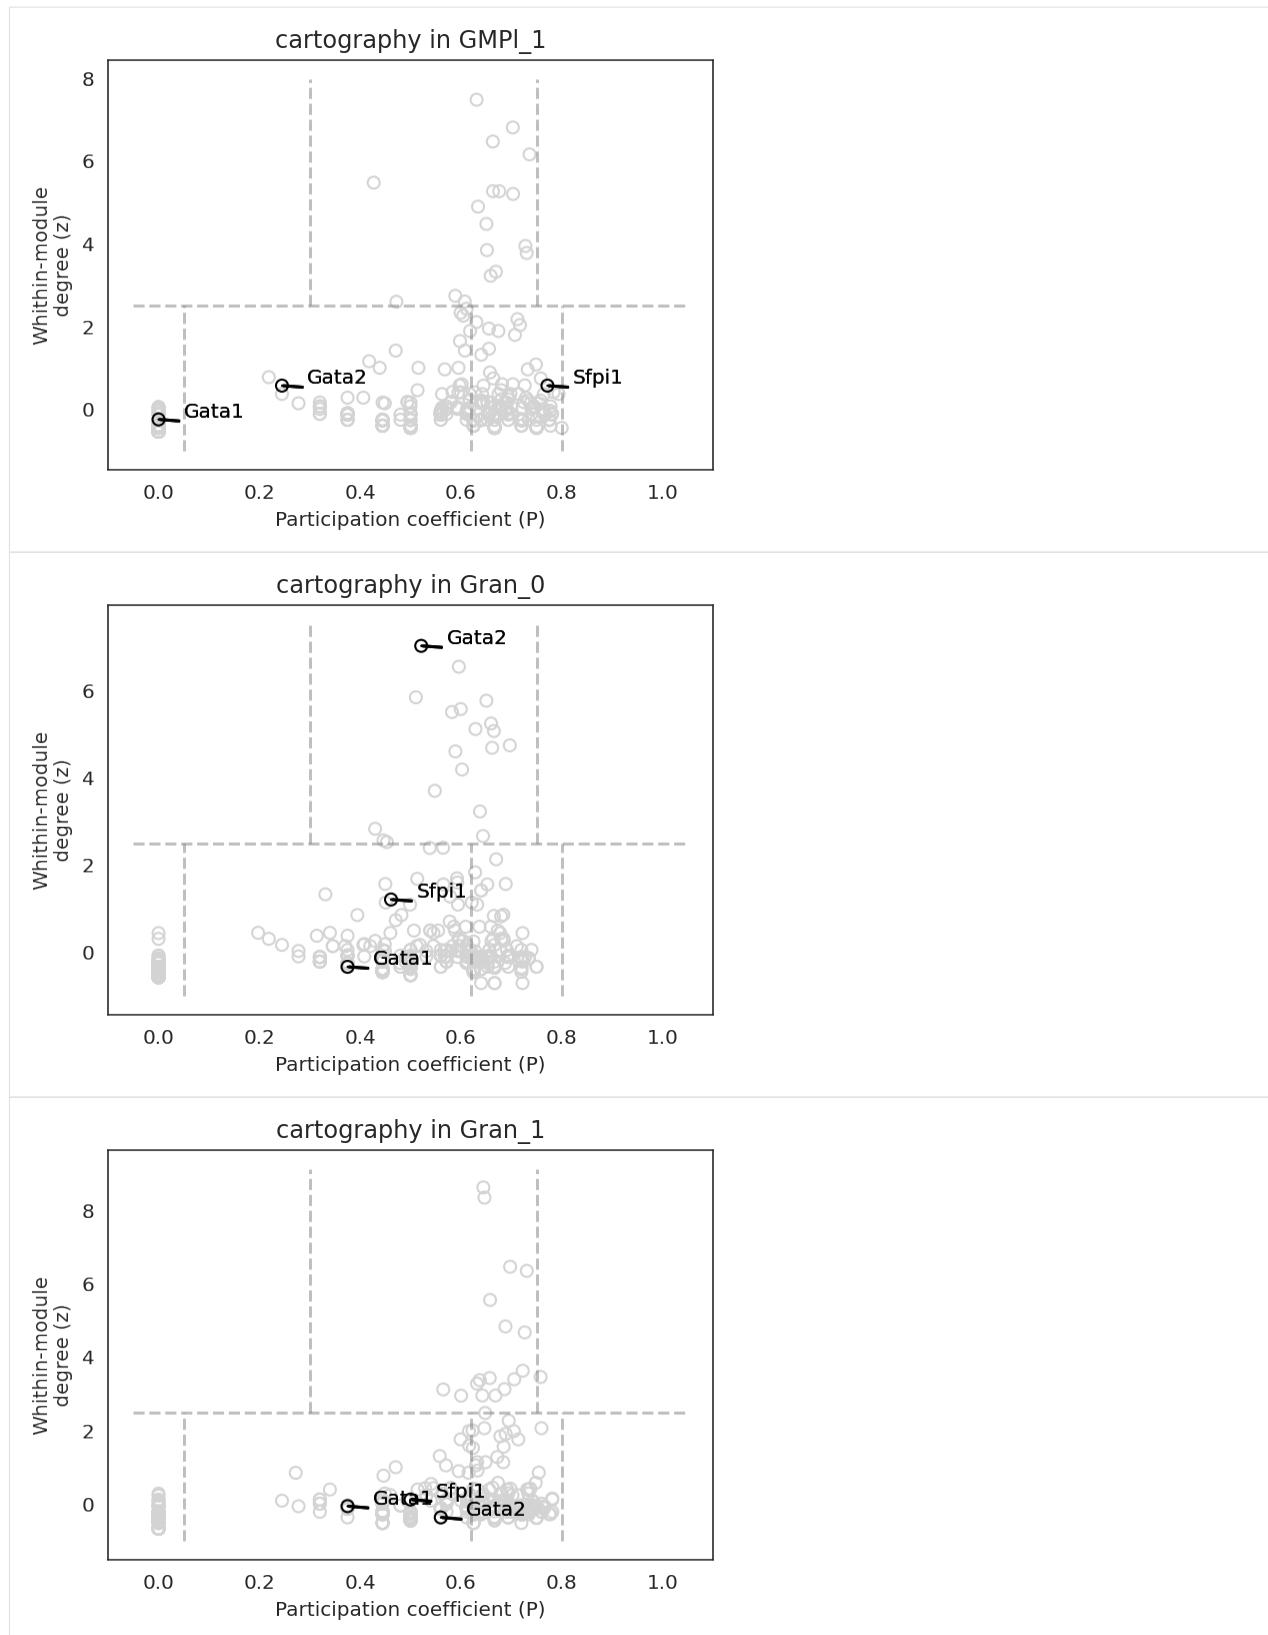

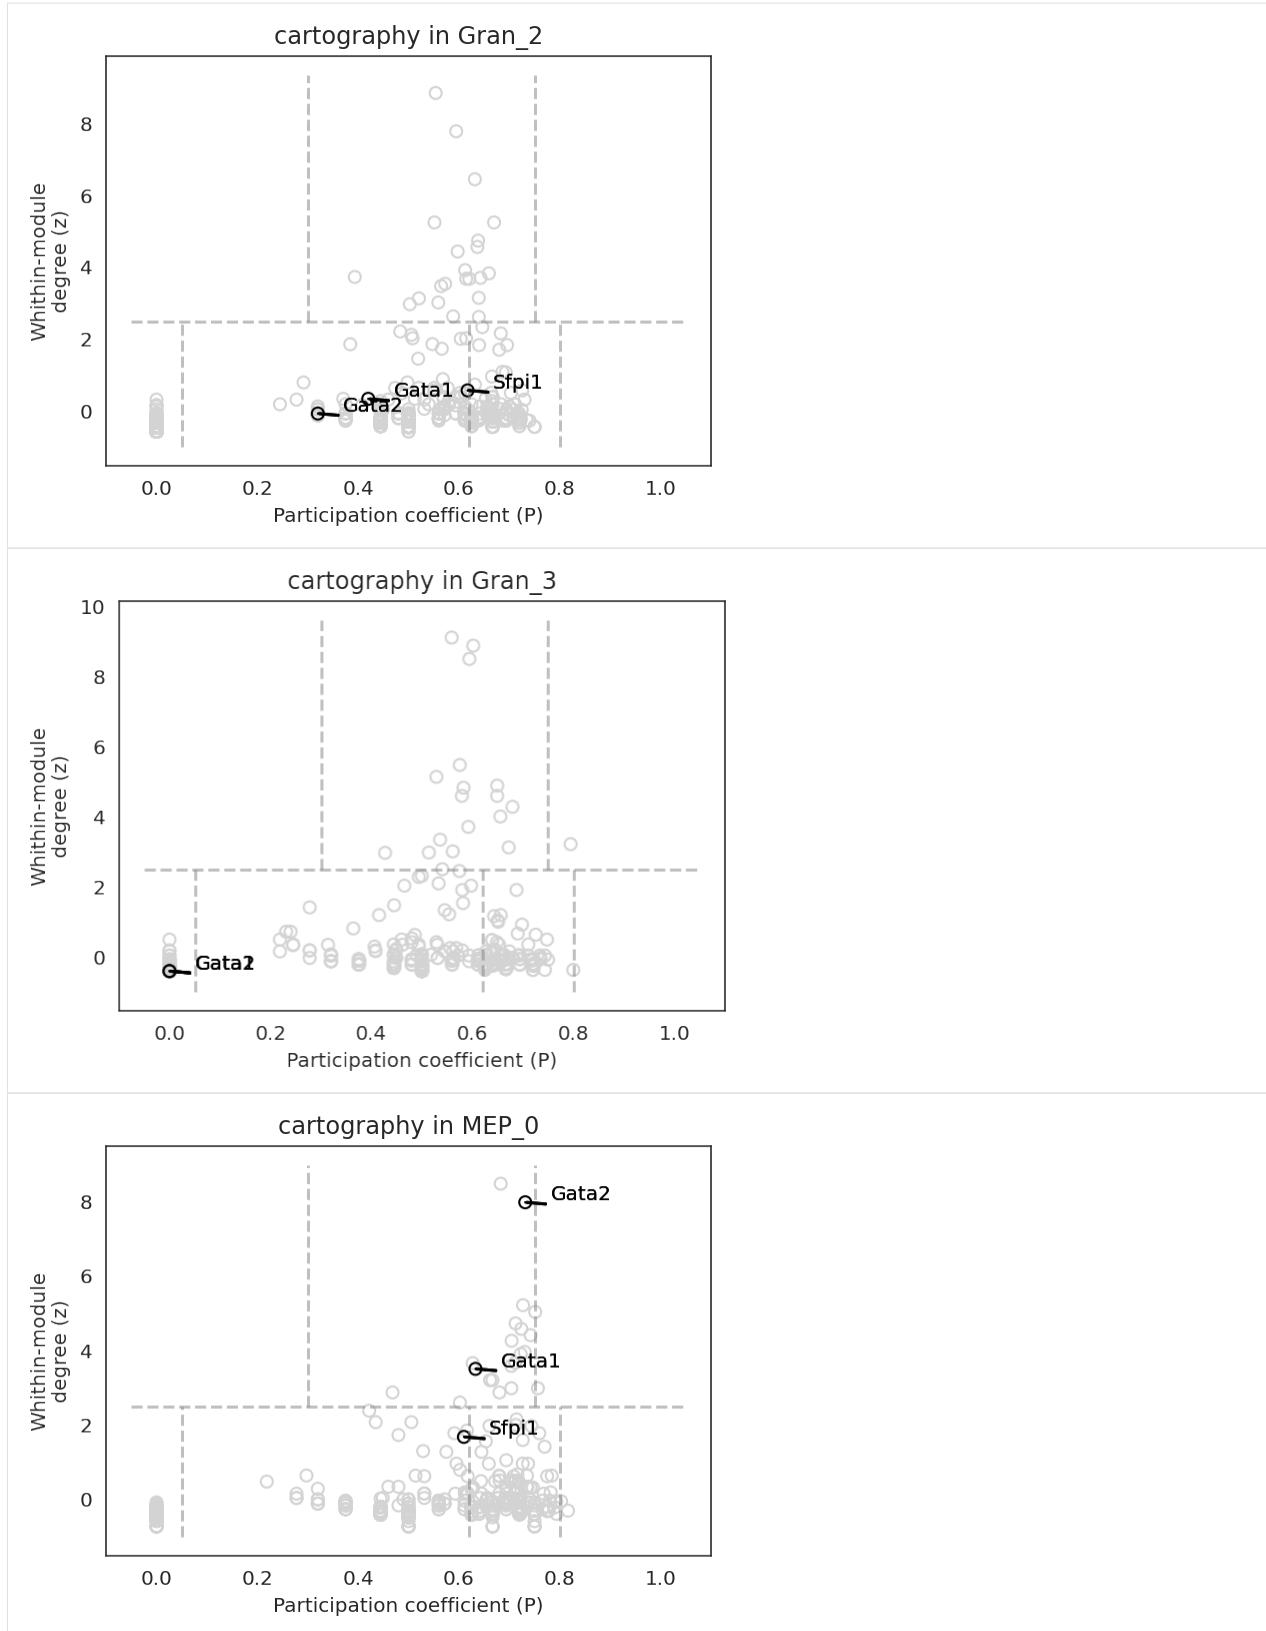

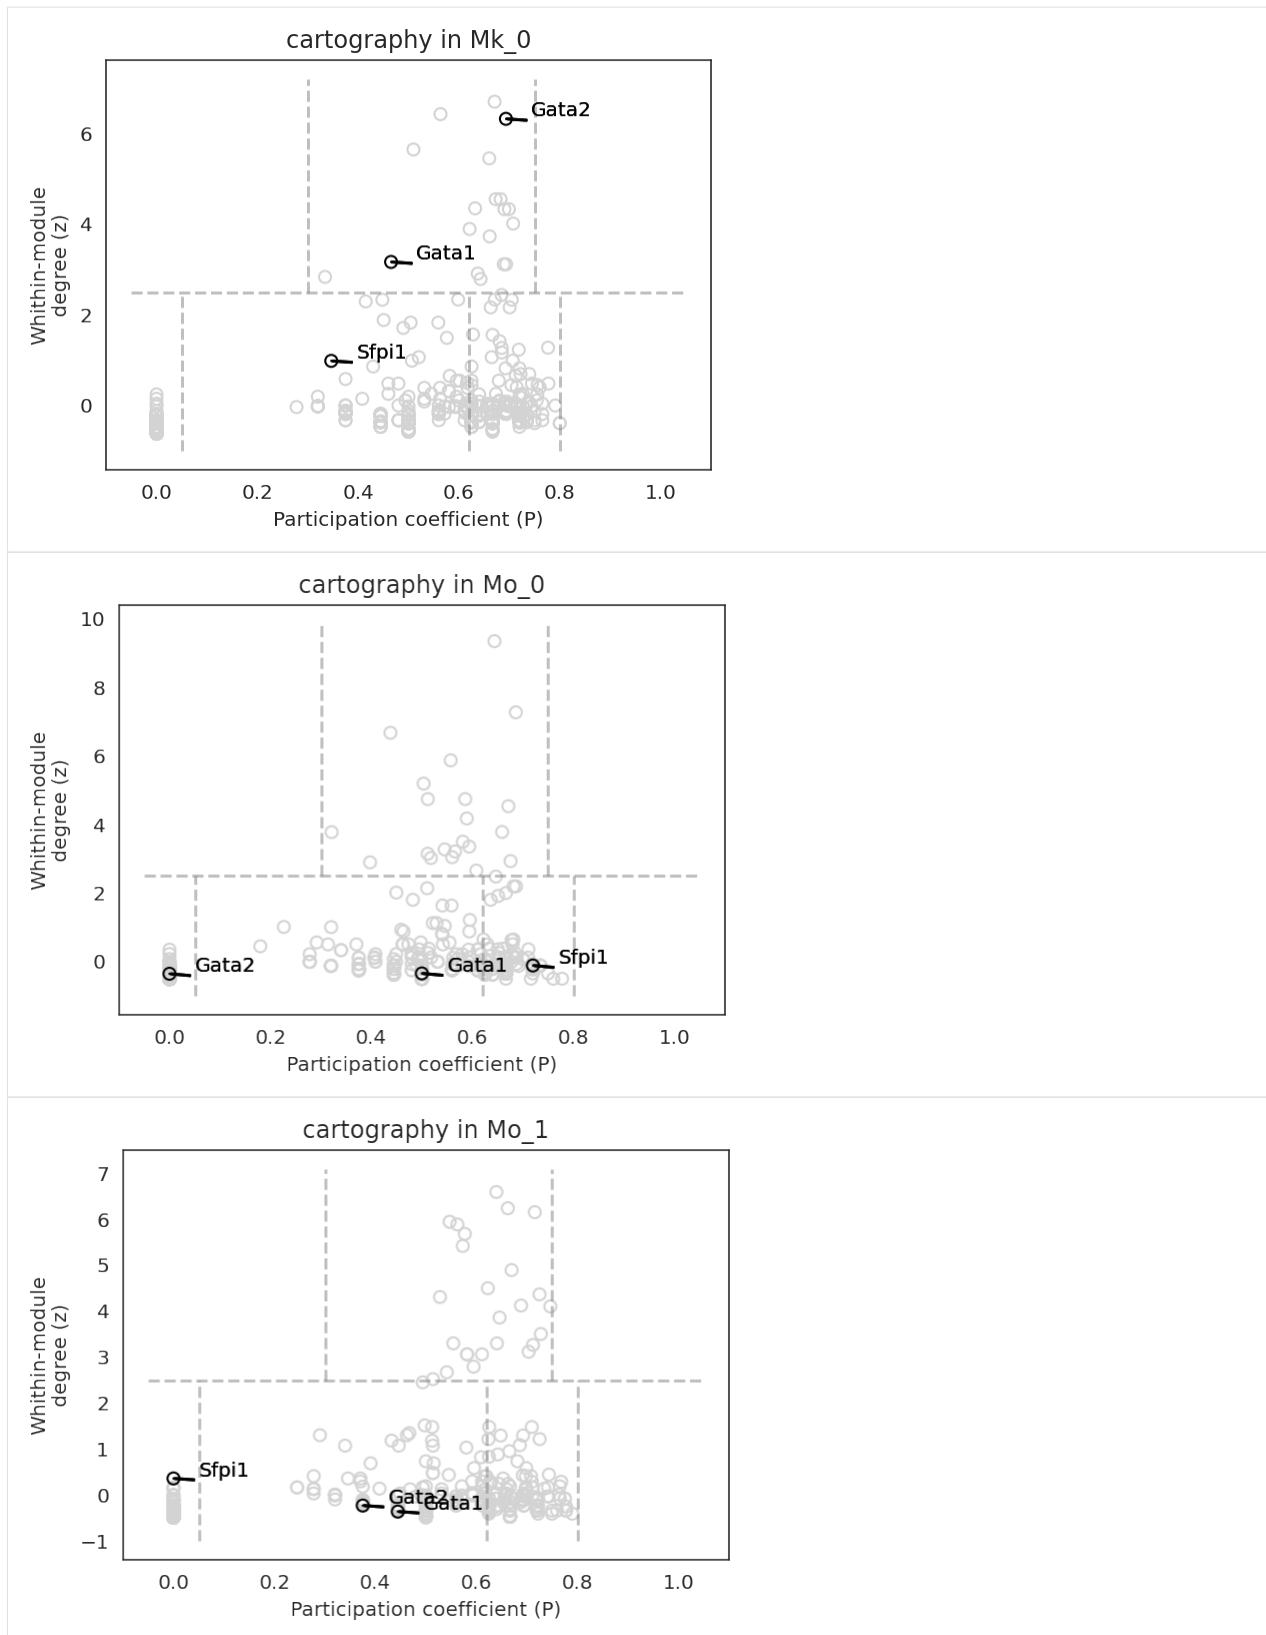

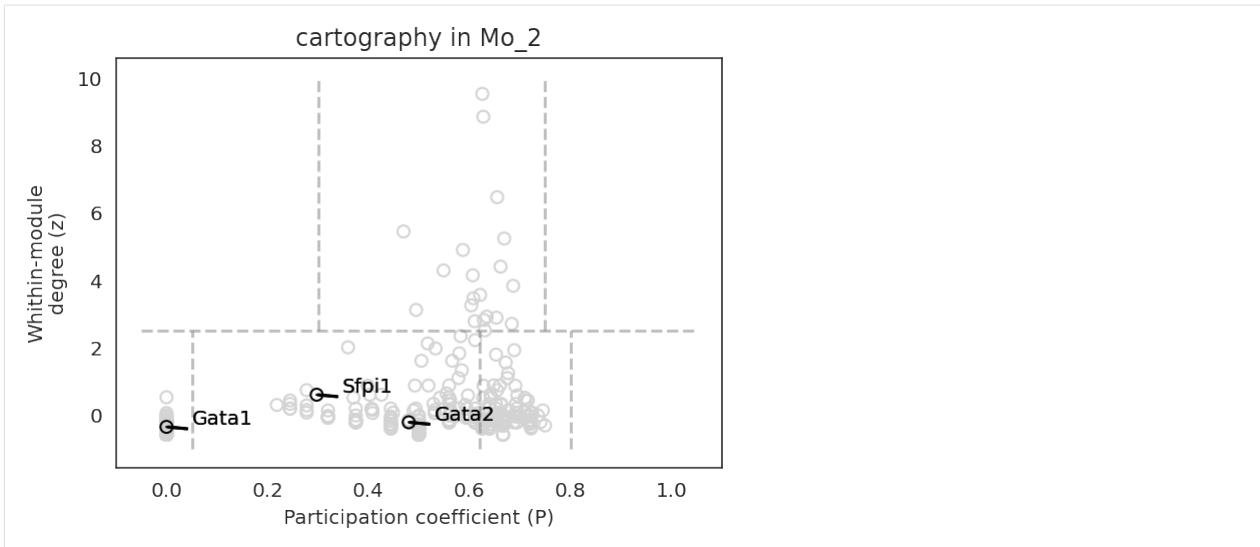

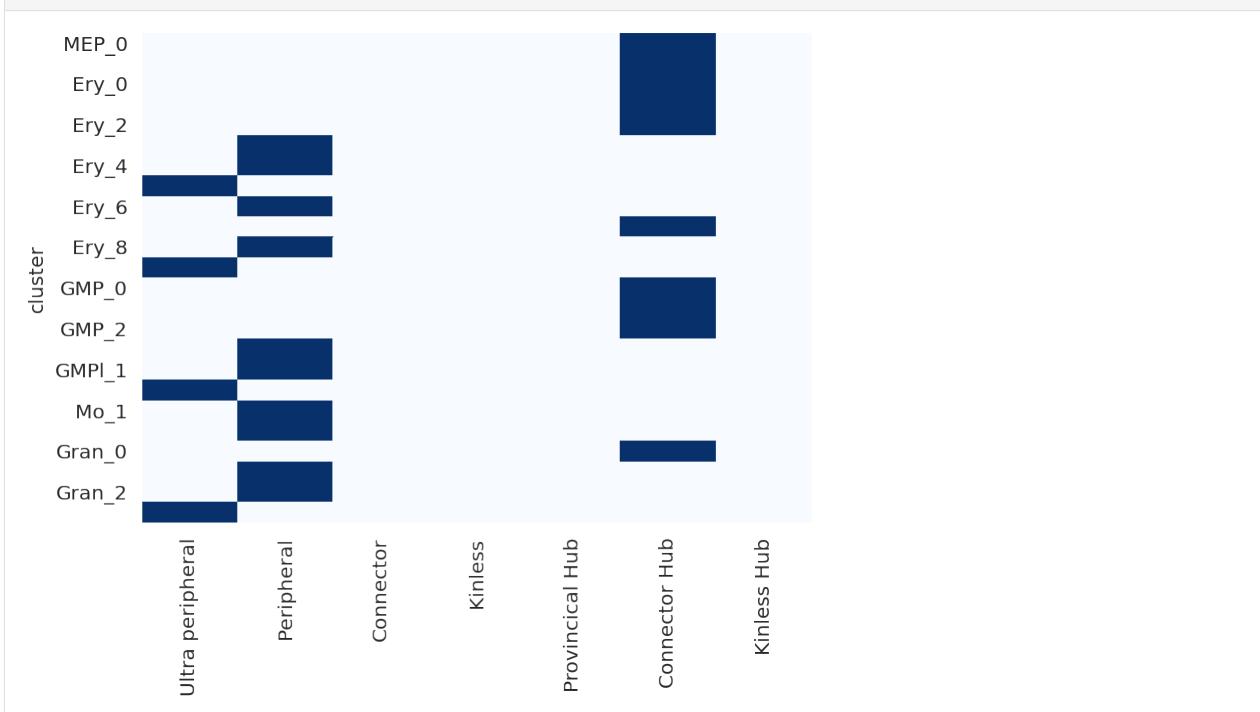

```
[65]: # Plot the summary of cartography analysis
links.plot_cartography_term(goi="Gata2", save=f"/{save_folder}/cartography")
```

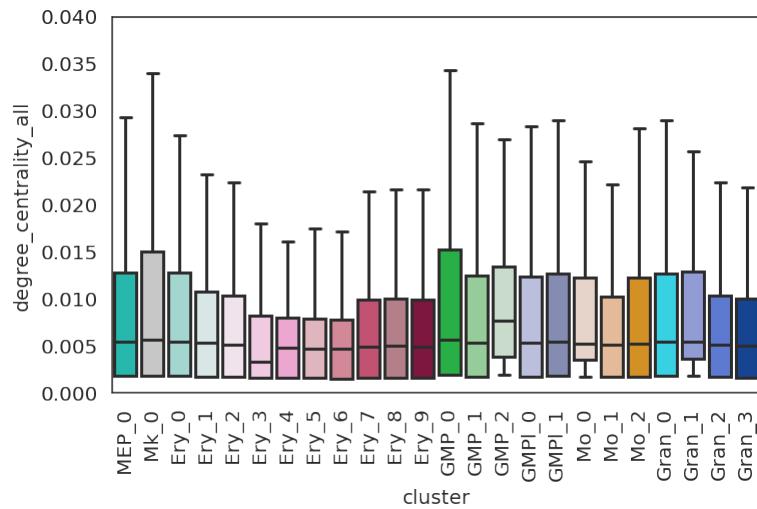

8. Network analysis; network score distribution

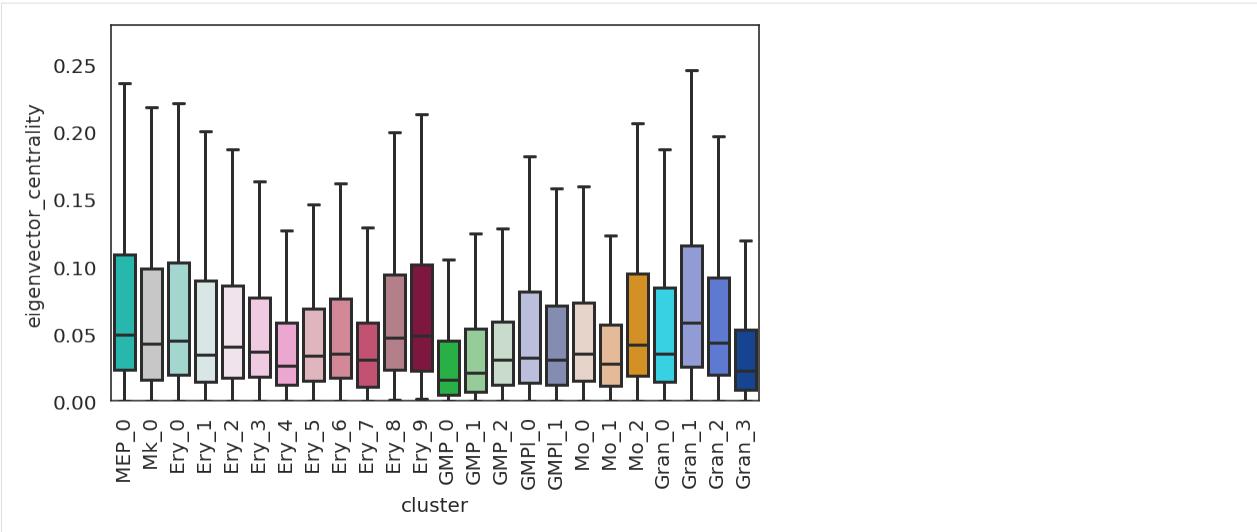

Next, we visualize the distribution of network score to get insight into the global trend of the GRNs.

8.1. Distribution of network degree

```
[66]: plt.subplots_adjust(left=0.15, bottom=0.3)
plt.ylim([0, 0.040])
links.plot_score_distributions(values=["degree_centrality_all"], method="boxplot", ↴
save=f" {save_folder}")
```

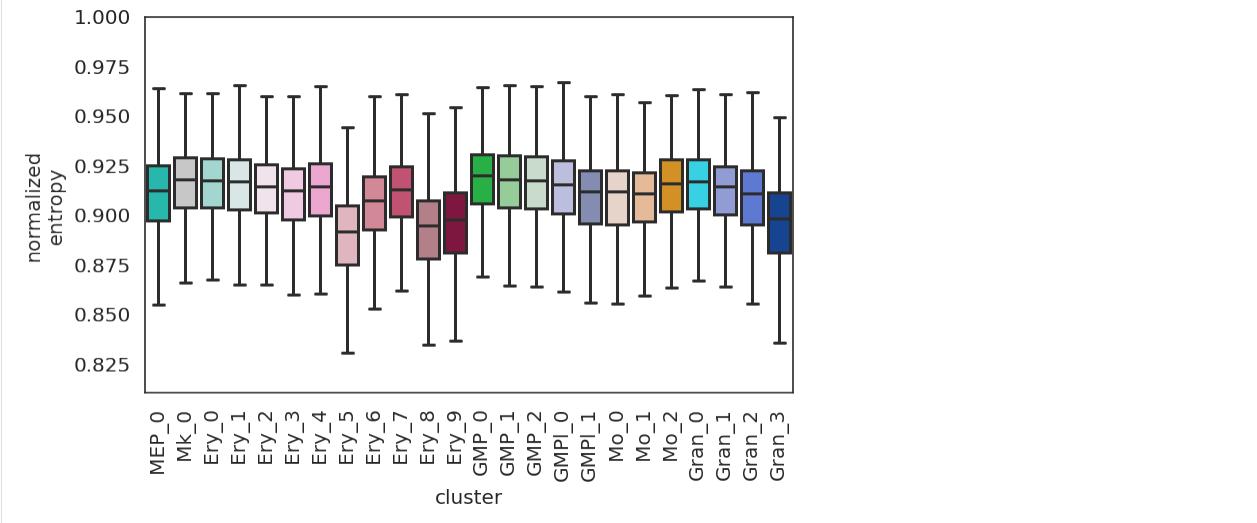

```
[69]: plt.subplots_adjust(left=0.15, bottom=0.3)
plt.ylim([0, 0.28])
links.plot_score_distributions(values=["eigenvector_centrality"], method="boxplot", ↴
save=f" {save_folder}")
```

8.2. Distribution of network entropy

```
[70]: plt.subplots_adjust(left=0.15, bottom=0.3)
links.plot_network_entropy_distributions(save=f'{save_folder}'")
```

Using the network scores, we could pick up cluster-specific key TFs. Gata2, Gata1, Klf1, E2f1, for example, are known to play an essential role in MEP, and these TFs showed high network score in our GRN.

However, it is important to note that network analysis alone cannot shed light on the specific functions or roles these TFs play in cell fate determination.

In the next section, we will begin to investigate each TF's contribution to cell fate by running GRN simulations

[]:

1.2.5 Simulation with GRNs

celloracle leverage GRNs to simulate signal propagation inside a cell. We can estimate the effect of gene perturbation by the simulation with GRNs.

Additionally, we will combine the signal propagation simulation with a cell state transition simulation. The latter simulation is performed by a python library for RNA-velocity analysis, called `velocyto`. This analysis may provide an insight into a complex system how TF controls enormous target genes to determines cell fate.

The jupyter notebook files and data used in this tutorial are available [here](#).

Python notebook

0. Import libraries

0.1. Import public libraries

```
[1]: import os
import sys

import matplotlib.colors as colors
import matplotlib.pyplot as plt
import numpy as np
import pandas as pd
import scanpy as sc
import seaborn as sns
```

This notebook was made with celloracle version 0.6.9. Please use `celloracle>=0.6.9`. Otherwise you may get an error.

```
[2]: import celloracle as co
co.__version__
[2]: '0.6.11'
```

```
[3]: #plt.rcParams["font.family"] = "arial"
plt.rcParams["figure.figsize"] = [9, 6]
%config InlineBackend.figure_format = 'retina'
plt.rcParams["savefig.dpi"] = 600

%matplotlib inline
```

0.1. Make a folder to save graph

```
[4]: # Make folder to save plots
save_folder = "figures"
os.makedirs(save_folder, exist_ok=True)
```

1. Load data

1.1. Load processed oracle object

Load the oracle object. See the previous notebook for the notes on how to prepare the oracle object.

```
[5]: # oracle = co.load_hdf5("ORACLE OBJECT PATH")

# Here, we load tutorial oracle object.
oracle = co.data.load_tutorial_oracle_object()
oracle
```

[5]: Oracle object

Meta data

```
    celloracle version used for instantiation: 0.6.11
    n_cells: 2671
    n_genes: 1999
    cluster_name: louvain_annot
    dimensional_reduction_name: X_draw_graph_fa
    k_for_knn_imputation: 66
```

Status

```
    Gene expression matrix: Ready
    BaseGRN: Ready
    PCA calculation: Done
    Knn imputation: Done
    GRN calculation for simulation: Not finished
```

1.2. Load inferred GRNs

In the previous notebook, we calculated GRNs. Now, we will use these GRNs for simulation. We import GRNs which were saved in the Links object.

```
[6]: # links = co.load_hdf5("YOUR LINK OBJCT PATH")

# Here, we load links object for tutorial.
links = co.data.load_tutorial_links_object()
```

2. Make predictive models for simulation

We will fit ridge regression models again. This process takes less time than the GRN inference in the previous notebook because we only use significant TFs to predict target gene instead of all regulatory candidate TFs.

```
[7]: links.filter_links()
oracle.get_cluster_specific_TFdict_from_Links(links_object=links)
oracle.fit_GRN_for_simulation(alpha=10, use_cluster_specific_TFdict=True)

HBox(children=(FloatProgress(value=0.0, max=1999.0), HTML(value='')))

HBox(children=(FloatProgress(value=0.0, max=1999.0), HTML(value='')))

HBox(children=(FloatProgress(value=0.0, max=1999.0), HTML(value='')))

HBox(children=(FloatProgress(value=0.0, max=1999.0), HTML(value='')))

HBox(children=(FloatProgress(value=0.0, max=1999.0), HTML(value='')))
```

```
HBox(children=(FloatProgress(value=0.0, max=1999.0), HTML(value='')))

HBox(children=(FloatProgress(value=0.0, max=1999.0), HTML(value='')))
```

3. in silico TF Perturbation analysis

Next, we will simulate the effects of perturbing a single TF to investigate its function and regulatory mechanism. See the celloracle paper for the details and scientific premise on the algorithm.

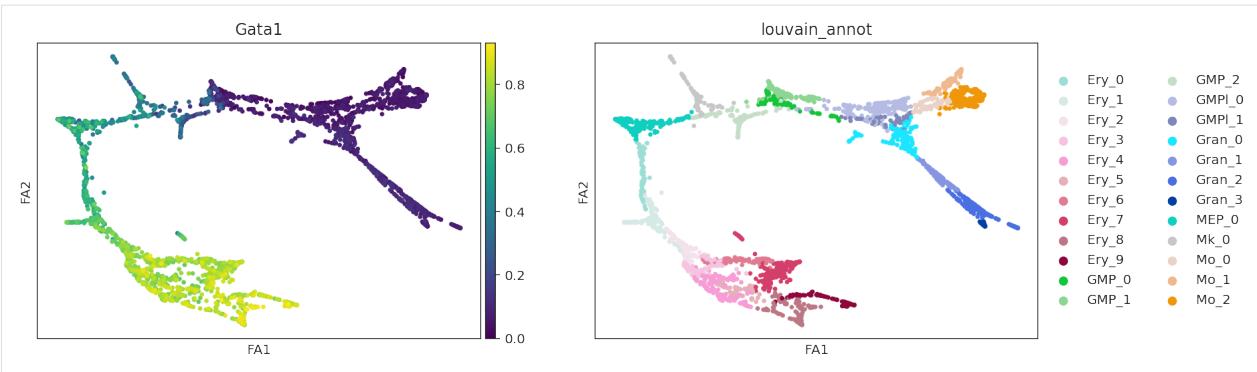

In this notebook, we'll show an example of the simulation; we'll simulate knock-out of Gata1 gene in the hematopoiesis.

Previous studies have shown that Gata1 is one of the TFs that regulates cell fate decisions in myeloid progenitors. Additionally, Gata1 has been shown to affect erythroid cell differentiation.

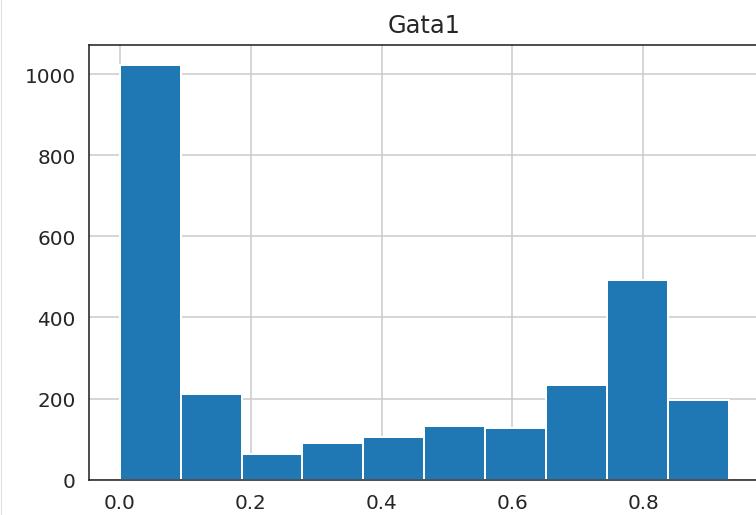

Here, we will analyze Gata1 for the demonstration of celloracle; Celloracle try to recapitulate the previous findings of Gata1 gene above.

3.1. Check gene expression pattern.

```
[8]: # Check gene expression
goi = "Gata1"
sc.pl.draw_graph(oracle.adata, color=[goi, oracle.cluster_column_name],
                 layer="imputed_count", use_raw=False, cmap="viridis")
```

```
[9]: # Plot gene expression in histogram
sc.get.obs_df(oracle.adata, keys=[goi], layer="imputed_count").hist()
plt.show()
```

3.2. calculate future gene expression after perturbation.

Although you can use any gene expression value for the input of in silico perturbation, please avoiding extremely high values which are far from natural gene expression ranges. The upper limit allowed is 2x of max gene expression value.

Here we simulate Gata1 KO; we predict what happens to the cells if Gata1 gene expression changed into 0.

```
[10]: # Enter perturbation conditions to simulate signal propagation after the perturbation.
oracle.simulate_shift(perturb_condition={goi: 0.0},
                      n_propagation=3)
```

3.3. calculate transition probability between cells

In the step above, we simulated future gene expression values after perturbation. This prediction is based on iterative calculations of signal propagations within the GRN.

Next step, we will calculate the probability of a cell state transition based on the simulated data. Using the transition probability between cells, we can predict how a cell changes after perturbation.

This transition probability will be used later.

```
[15]: # Get transition probability
oracle.estimate_transition_prob(n_neighbors=200, knn_random=True, sampled_fraction=1)

# Calculate embedding
oracle.calculate_embedding_shift(sigma_corr = 0.05)
```

4. Visualization

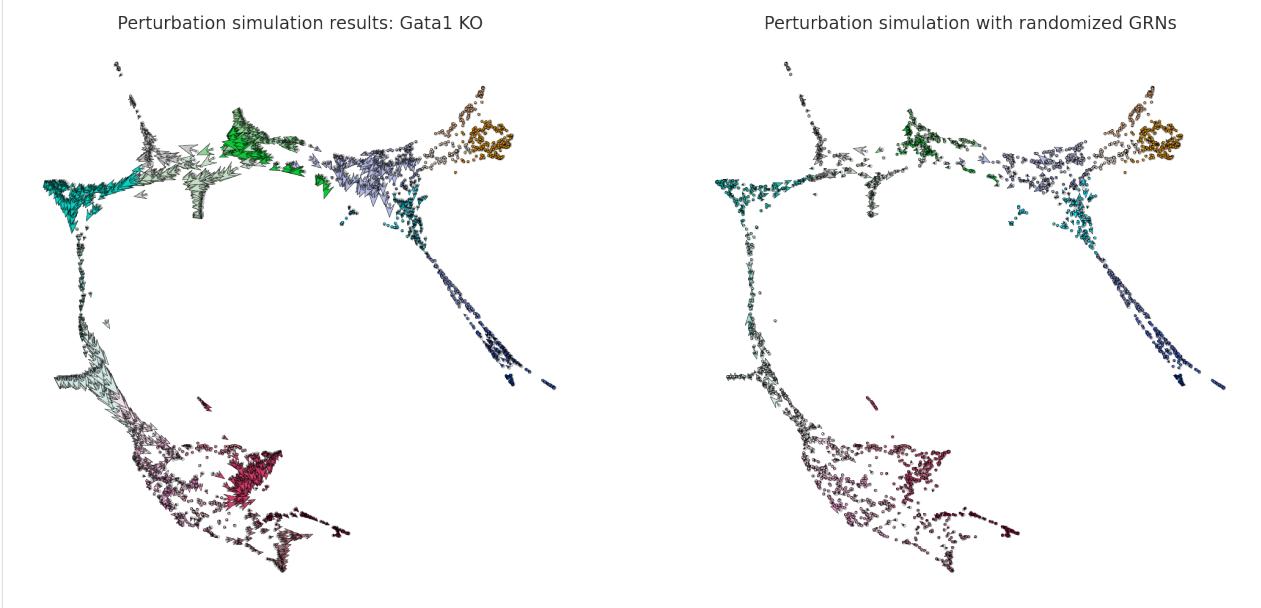

4.1. Quiver plot: Show the direction of cell transition at single cell resolution

```
[16]: fig, ax = plt.subplots(1, 2, figsize=[15, 7])

scale = 30
# Show quiver plot
oracle.plot_quiver(scale=scale, ax=ax[0])
ax[0].set_title(f"Perturbation simulation results: {goi} KO")

# Show quiver plot that was calculated with randomized GRN.
oracle.plot_quiver_random(scale=scale, ax=ax[1])
ax[1].set_title(f"Perturbation simulation with randomized GRNs")

plt.show()
```

4.2. Vector field graph

We can visualize simulation result as a vector field graph. Single cell transition vectors are grouped by grid point.

- The grid point that have few cells are removed. Please adjust `min_mass` if you get too many or too less grid point.

```
[17]: oracle.calculate_p_mass(smooth=0.8, n_grid=40, n_neighbors=200)
oracle.calculate_mass_filter(min_mass=0.01)
```

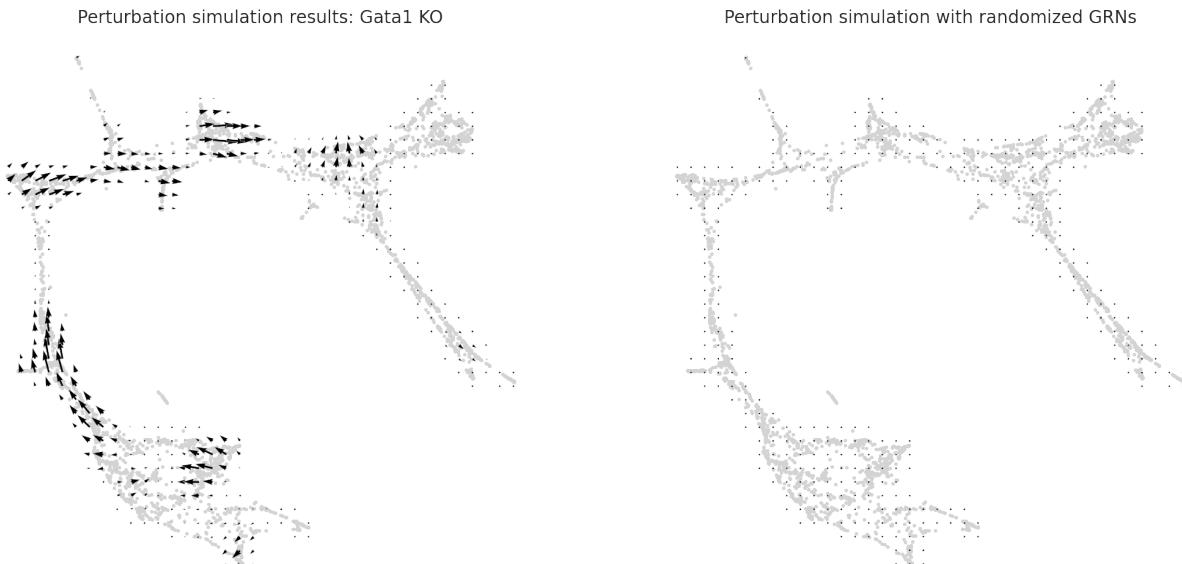

please adjust `scale` parameter. Plesase try to find optimal `scale` parameter that give you good visualization. If you see don't see any vector, you can try smaller `scale` parameter. But if you see some vectors in the right panel, which is the randomized simulation, it means the `scale` parameter is too small.

```
[18]: fig, ax = plt.subplots(1, 2, figsize=[15, 7])

scale_grid = 0.8
# Show quiver plot
oracle.plot_simulation_flow_on_grid(scale=scale_grid, ax=ax[0])
ax[0].set_title(f"Perturbation simulation results: {goi} KO")

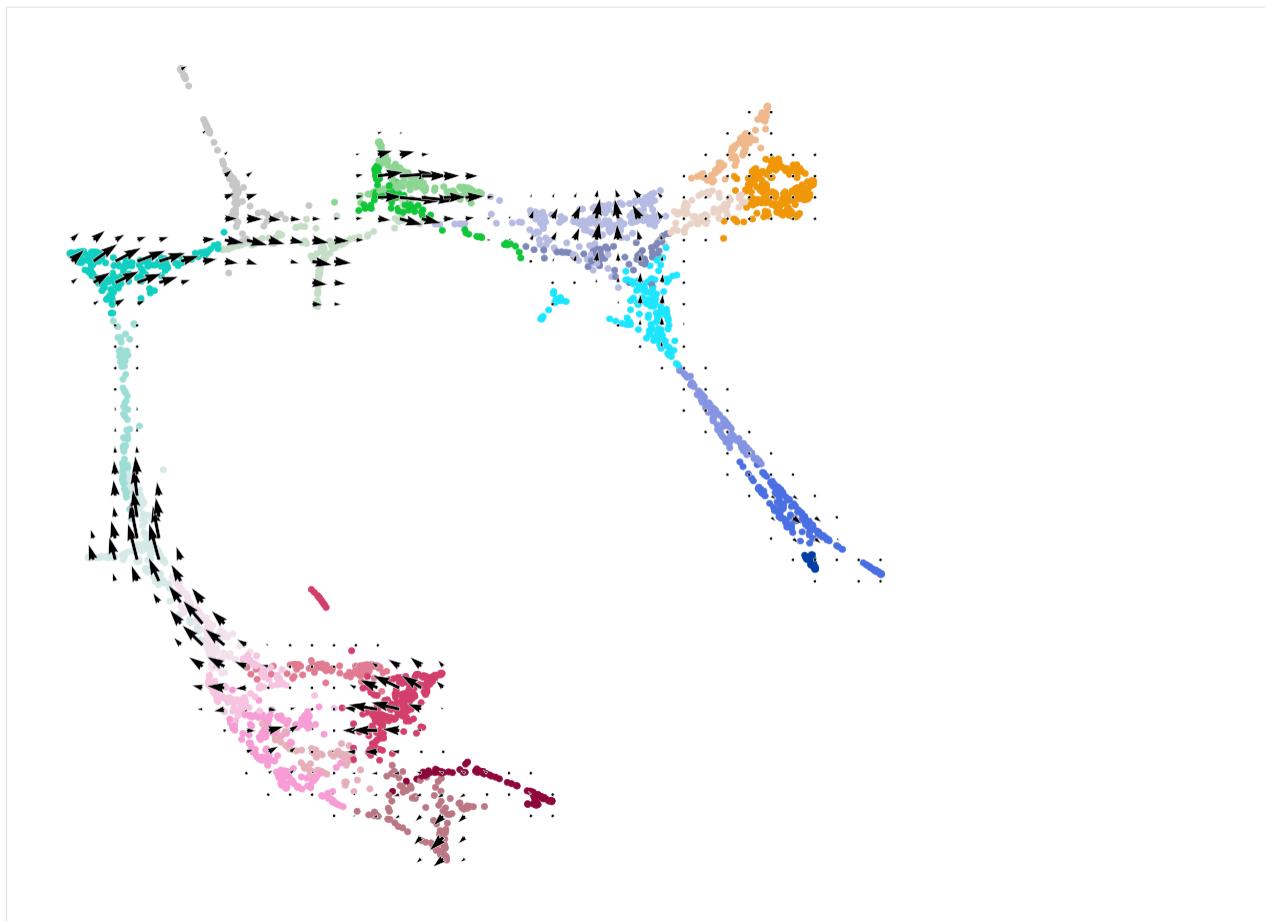

# Show quiver plot that was calculated with randomized GRN.
oracle.plot_simulation_flow_random_on_grid(scale=scale_grid, ax=ax[1])
ax[1].set_title(f"Perturbation simulation with randomized GRNs")

plt.show()
```

```
[19]: # Plot vector field with cell cluster
fig, ax = plt.subplots(figsize=[8, 8])

oracle.plot_cluster_whole(ax=ax, s=10)
oracle.plot_simulation_flow_on_grid(scale=scale_grid, ax=ax, show_background=False)
```

Based on the results, we may conclude several things as follows.

Gata1 KO induced both cell state transitions from Erythroids to MEP, and from MEP to GMP.

- (1) These results suggest that Gata1 may play a role in the progression of Erythroid differentiation and cell state determination between the MEP and GMP lineages.
- (2) Gata1 KO also induced cell state transitions from granulocytes to late GMP, suggesting Gata1's involvement in Granulocytes differentiation.

These results agree with previous reports about Gata1 and recapitulate Gata1's cell-type-specific function regarding the cell fate decisions in hematopoiesis.

1.3 Google Colaboratory

Let's try CellOracle tutorials in Google Colaboratory environment. You can easily run celloracle using built-in dataset.
- scRNA-seq data: hematopoiesis data published by Paul et.al (2015). - base GRN: mouse sci-ATAC-atlas dataset

1.3.1 Setup CellOracle in Google Colab

celloracle uses several python libraries and R library. Please run the notebook in Google Colab. All dependent software will be installed.

- `Install CellOracle and its requirements in Google Colaboratory ` .

1.3.2 Network analysis with Hematopoiesis dataset

- `Run notebook for Network analysis in Google Colab ` .

1.3.3 CellOracle TF perturbation simulation

- `Run notebook for perturbation simulation in Google Colab ` .

1.4 API

1.4.1 Command Line API

CellOracle has a command line API. This command can be used to convert scRNA-seq data. If you have a scRNA-seq data which was processed with Seurat and saved as Rds file, you can use the following command to make anndata from Seurat object. The anndata object produced by this command can be used for input of celloracle.

```
seuratToAnndata YOUR_SEURAT_OBJECT.Rds OUTPUT_PATH
```

1.4.2 Python API

Custom class in celloracle

We define some custom classes in celloracle.

```
class celloracle.Links(name, links_dict={})  
    Bases: object
```

This is a class for the processing and visualization of GRNs. Links object stores cluster-specific GRNs and metadata. Please use “get_links” function in Oracle object to generate Links object.

```
links_dict  
    Dictionary that store unprocessed network data.
```

Type dictionary

filtered_links
Dictionary that store filtered network data.

Type dictionary

merged_score
Network scores.

Type pandas.dataframe

cluster
List of cluster name.

Type list of str

name
Name of clustering unit.

Type str

palette
DataFrame that store color information.

Type pandas.dataframe

filter_links (*p=0.001, weight='coef_abs', thread_number=10000, genelist_source=None, genelist_target=None*)
Filter network edges. In most cases, inferred GRN has non-significant random edges. We have to remove these edges before analyzing the network structure. You can do the filtering in any of the following ways.

- (1) Filter based on the p-value of the network edge. Please enter p-value for thresholding.
- (2) Filter based on network edge number. If you set the number, network edges will be filtered based on the order of a network score. The top n-th network edges with network weight will remain, and the other edges will be removed. The network data has several types of network weight, so you have to select which network weight do you want to use.
- (3) Filter based on an arbitrary gene list. You can set a gene list for source nodes or target nodes.

Parameters

- **p** (*float*) – threshold for p-value of the network edge.
- **weight** (*str*) – Please select network weight name for the filtering
- **genelist_source** (*list of str*) – gene list to remain in regulatory gene nodes. Default is None.
- **genelist_target** (*list of str*) – gene list to remain in target gene nodes. Default is None.

get_network_entropy (*value='coef_abs'*)
Calculate network entropy scores.

Parameters **value** (*str*) – Default is “coef_abs”.

get_score (*test_mode=False*)
Get several network scores using R libraries. Make sure all dependent R libraries are installed in your environment before running this function. You can check the installation for the R libraries by running `test_installation()` in `network_analysis` module.

```
plot_cartography_scatter_per_cluster(gois=None,      clusters=None,      scatter=True,
                                      kde=False,       auto_gene_annot=False,    per-
                                      centile=98,     args_dot={'n_levels':      105},
                                      args_line={'c':      'gray'},    args_annot={},
                                      save=None)
```

Make a gene network cartography plot. Please read the original paper describing gene network cartography for more information. <https://www.nature.com/articles/nature03288>

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **gois** (*list of str*) – List of gene name to highlight.
- **clusters** (*list of str*) – List of cluster name to analyze. If None, all clusters in `Links` object will be analyzed.
- **scatter** (*bool*) – Whether to make a scatter plot.
- **auto_gene_annot** (*bool*) – Whether to pick up genes to make an annotation.
- **percentile** (*float*) – Genes with a network score above the percentile will be shown with annotation. Default is 98.
- **args_dot** (*dictionary*) – Arguments for scatter plot.
- **args_line** (*dictionary*) – Arguments for lines in cartography plot.
- **args_annot** (*dictionary*) – Arguments for annotation in plots.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

plot_cartography_term (*goi*, *save=None*, *plt_show=True*)

Plot the gene network cartography term like a heatmap. Please read the original paper of gene network cartography for the principle of gene network cartography. <https://www.nature.com/articles/nature03288>

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **gois** (*list of str*) – List of gene name to highlight.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

plot_degree_distributions (*plot_model=False*, *save=None*)

Plot the network degree distributions (the number of edge per gene). The network degree will be visualized in both linear scale and log scale.

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **plot_model** (*bool*) – Whether to plot linear approximation line.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

plot_network_entropy_distributions (*update_network_entropy=False*, *save=None*)

Plot the distribution for network entropy. See the CellOracle paper for more detail.

Parameters

- **links** (*Links object*) – See `network_analysis.Links` class for detail.

- **values** (*list of str*) – The list of score to visualize. If it is None, all network score (listed above) will be used.
- **update_network_entropy** (*bool*) – Whether to recalculate network entropy.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

plot_score_comparison_2D (*value, cluster1, cluster2, percentile=99, annot_shifts=None, save=None, plt_show=True, interactive=False*)

Make a scatter plot that compares specific network scores in two groups.

Parameters

- **links** ([Links](#)) – See network_analysis.Links class for detail.
- **value** (*srt*) – The network score type.
- **cluster1** (*str*) – Cluster name. Network scores in cluster1 will be visualized in the x-axis.
- **cluster2** (*str*) – Cluster name. Network scores in cluster2 will be visualized in the y-axis.
- **percentile** (*float*) – Genes with a network score above the percentile will be shown with annotation. Default is 99.
- **annot_shifts** ((*float, float*)) – Annotation visualization setting.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

plot_score_distributions (*values=None, method='boxplot', save=None*)

Plot the distribution of network scores. An individual data point is a network edge (gene).

Parameters

- **links** ([Links](#)) – See Links class for details.
- **values** (*list of str*) – The list of score to visualize. If it is None, all of the network score will be used.
- **method** (*str*) – Plotting method. Select either “boxplot” or “barplot”.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

plot_score_per_cluster (*goi, save=None, plt_show=True*)

Plot network score for a gene. This function visualizes the network score for a specific gene between clusters to get an insight into the dynamics of the gene.

Parameters

- **links** ([Links](#)) – See network_analysis.Links class for detail.
- **goi** (*srt*) – Gene name.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

plot_scores_as_rank (*cluster, n_gene=50, save=None*)

Pick up top n-th genes with high-network scores and make plots.

Parameters

- **links** ([Links](#)) – See network_analysis.Links class for detail.

- **cluster** (*str*) – Cluster name to analyze.
- **n_gene** (*int*) – Number of genes to plot. Default is 50.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

to_hdf5 (*file_path*)

Save object as hdf5.

Parameters **file_path** (*str*) – file path to save file. Filename needs to end with ‘.celloracle.links’

class `celloracle.Net` (*gene_expression_matrix*, *gem_standerdized=None*, *TFinfo_matrix=None*, *cell-state=None*, *TFinfo_dic=None*, *annotation=None*, *verbose=True*)

Bases: `object`

Net is a custom class for inferring sample-specific GRN from scRNA-seq data. This class is used inside the Oracle class for GRN inference. This class requires two types of information below.

- (1) Single-cell RNA-seq data: The Net class needs processed scRNA-seq data. Gene and cell filtering, quality check, normalization, log-transformation (but not scaling and centering) have to be done before starting the GRN calculation with this class. You can also use any arbitrary metadata (i.e., mRNA count, cell-cycle phase) for GRN input.
- (2) Potential regulatory connection (or base GRN): This method uses the list of potential regulatory TFs as input. This information can be calculated from ATAC-seq data using the motif-analysis module. If sample-specific ATAC-seq data is not available, you can use general TF-binding info derived from public ATAC-seq dataset of various tissue/cell type.

linkList

The results of the GRN inference.

Type `pandas.DataFrame`

all_genes

An array of all genes that exist in the input gene expression matrix

Type `numpy.array`

embedding_name

The key name name in `adata.obsm` containing dimensional reduction coordinates

Type `str`

annotation

Annotation. you can add custom annotation.

Type `dictionary`

coefs_dict

Coefs of linear regression.

Type `dictionary`

stats_dict

Statistic values about coefs.

Type `dictionary`

fitted_genes

List of genes where the regression model was successfully calculated.

Type `list of str`

failed_genes

List of genes that were not assigned coeffs

Type list of str

cellstate

A metadata for GRN input

Type pandas.DataFrame

TFinfo

Information about potential regulatory TFs.

Type pandas.DataFrame

gem

Merged matrix made with gene_expression_matrix and cellstate matrix.

Type pandas.DataFrame

gem_standerdized

Almost the same as gem, but the gene_expression_matrix was standarized.

Type pandas.DataFrame

library_last_update_date

Last update date of this code. This info is for code development. It can be deprecated in the future

Type str

object_initiation_date

The date when this object was made.

Type str

addAnnotation (annotation_dictionary)

Add a new annotation.

Parameters **annotation_dictionary** (*dictionary*) – e.g. {“sample_name”: “NIH 3T3 cell”}

addTFinfo_dictionary (TFdict)

Add a new TF info to pre-existing TFdict.

Parameters **TFdict** (*dictionary*) – python dictionary of TF info.

addTFinfo_matrix (TFinfo_matrix)

Load TF info dataframe.

Parameters **TFinfo** (*pandas.DataFrame*) – information about potential regulatory TFs.

copy ()

Deepcopy itself

fit_All_genes (bagging_number=200, scaling=True, model_method='bagging_ridge', command_line_mode=False, log=None, alpha=1, verbose=True)

Make ML models for all genes. The calculation will be performed in parallel using scikit-learn bagging function. You can select a modeling method (bagging_ridge or bayesian_ridge). This calculation usually takes a long time.

Parameters

- **bagging_number** (*int*) – The number of estimators for bagging.
- **scaling** (*bool*) – Whether or not to scale regulatory gene expression values.

- **model_method** (*str*) – ML model name. Please select either “bagging_ridge” or “bayesian_ridge”
- **command_line_mode** (*bool*) – Please select False if the calculation is performed on jupyter notebook.
- **log** (*logging object*) – log object to output log
- **alpha** (*int*) – Strength of regularization.
- **verbose** (*bool*) – Whether or not to show a progress bar.

fit_All_genes_parallel (*bagging_number=200, scaling=True, log=None, verbose=10*)

IMPORTANT: this function being debugged and is currently unavailable.

Make ML models for all genes. The calculation will be performed in parallel using joblib parallel module.

Parameters

- **bagging_number** (*int*) – The number of estimators for bagging.
- **scaling** (*bool*) – Whether or not to scale regulatory gene expression values.
- **log** (*logging object*) – log object to output log
- **verbose** (*int*) – verbose for joblib parallel

fit_genes (*target_genes, bagging_number=200, scaling=True, model_method='bagging_ridge', save_coefs=False, command_line_mode=False, log=None, alpha=1, verbose=True*)

Make ML models for genes of interest. This calculation will be performed in parallel using scikit-learn’s bagging function. You can select a modeling method; Please chose either bagging_ridge or bayesian_ridge.

Parameters

- **target_genes** (*list of str*) – gene list
- **bagging_number** (*int*) – The number of estimators for bagging.
- **scaling** (*bool*) – Whether or not to scale regulatory gene expression values.
- **model_method** (*str*) – ML model name. Please select either “bagging_ridge” or “bayesian_ridge”
- **save_coefs** (*bool*) – Whether or not to store details of coef values in bagging model.
- **command_line_mode** (*bool*) – Please select False if the calculation is performed on jupyter notebook.
- **log** (*logging object*) – log object to output log
- **alpha** (*int*) – Strength of regularization.
- **verbose** (*bool*) – Whether or not to show a progress bar.

plotCoefs (*target_gene, sort=True, threshold_p=None*)

Plot the distribution of Coef values (network edge weights).

Parameters

- **target_gene** (*str*) – gene name
- **sort** (*bool*) – Whether or not to sort genes by its strength
- **bagging_number** (*int*) – The number of estimators for bagging.
- **threshold_p** (*float*) – the threshold for p-values. TFs will be filtered based on the p-value. if None, no filtering is applied.

to_hdf5 (file_path)
Save object as hdf5.

Parameters `file_path` (`str`) – file path to save file. Filename needs to end with ‘.celloracle.net’

updateLinkList (verbose=True)
Update LinkList. LinkList is a data frame that store information about inferred GRNs.

Parameters `verbose` (`bool`) – Whether or not to show a progress bar

updateTFinfo_dictionary (TFdict)
Update TF info matrix

Parameters `TFdict` (`dictionary`) – A python dictionary in which a key is Target gene, value are potential regulatory genes for the target gene.

class celloracle.Oracle
Bases: `celloracle.trajectory.modified_VelocytoLoom_class`.
`modified_VelocytoLoom`, `celloracle.visualizations.oracle_object_visualization`.
`Oracle_visualization`

Oracle is the main class in CellOracle. Oracle object imports scRNA-seq data (anndata) and TF information to infer cluster-specific GRNs. It can predict the future gene expression patterns and cell state transitions in response to the perturbation of TFs. Please see the CellOracle paper for details. The code of the Oracle class was made of the three components below.

- (1) Anndata: Gene expression matrix and metadata from single-cell RNA-seq are stored in the anndata object. Processed values, such as normalized counts and simulated values, are stored as layers of anndata. Metadata (i.e., Cluster info) are saved in anndata.obs. Refer to scanpy/anndata documentation for detail.
- (2) Net: Net is a custom class in celloracle. Net object processes several data to infer GRN. See the Net class documentation for details.
- (3) VelocytoLoom: Calculation of transition probability and visualization of directed trajectory graph will be performed in the same way as velocytoloom. VelocytoLoom is class from Velocyto, a python library for RNA-velocity analysis. In celloracle, we use some functions in velocytoloom for the visualization.

adata
Imported anndata object

Type anndata

cluster_column_name
The column name in adata.obs containing cluster info

Type str

embedding_name
The key name in adata.obsm containing dimensional reduction cordinates

Type str

addTFinfo_dictionary (TFdict)
Add new TF info to pre-existing TFdict. Values in the old TF dictionary will remain.

Parameters `TFdict` (`dictionary`) – Python dictionary of TF info.

calculate_mass_filter (min_mass=0.01, plot=False)

calculate_p_mass (smooth=0.8, n_grid=40, n_neighbors=200, n_jobs=-1)

change_cluster_unit (*new_cluster_column_name*)

Change clustering unit. If you change cluster, previous GRN data and simulation data will be deleted. Please re-calculate GRNs.

copy ()

Deepcopy itself.

count_cells_in_mc_resutls (*cluster_use*, *end=-1*, *order=None*)

Count the simulated cell by the cluster.

Parameters

- **cluster_use** (*str*) – cluster information name in anndata.obs. You can use any cluster information in anndata.obs.
- **end** (*int*) – The end point of Sankey-diagram. Please select a step in the Markov simulation. if you set [end=-1], the final step of Markov simulation will be used.

Returns Number of cells before / after simulation

Return type pandas.DataFrame

extract_active_gene_lists (*return_as=None*, *verbose=False*)**Parameters**

- **return_as** (*str*) – If not None, it returns dictionary or list. Chose either “individual_dict” or “unified_list”.
- **verbose** (*bool*) – Whether to show progress bar.

Returns The format depends on the argument, “return_as”.

Return type dictionary or list

fit_GRN_for_simulation (*GRN_unit='cluster'*, *alpha=1*, *use_cluster_specific_TFdict=False*)

Do GRN inference. Please see the paper of CellOracle paper for details.

GRN can be constructed for the entire population or each clusters. If you want to infer cluster-specific GRN, please set [GRN_unit=”cluster”]. You can select cluster information when you import data.

If you set [GRN_unit=”whole”], GRN will be made using all cells.

Parameters

- **GRN_unit** (*str*) – Select “cluster” or “whole”
- **alpha** (*float or int*) – The strength of regularization. If you set a lower value, the sensitivity increases, and you can detect weaker network connections. However, there may be more noise. If you select a higher value, it will reduce the chance of overfitting.

get_cluster_specific_TFdict_from_Links (*links_object*)

Extract TF and its target gene information from Links object. This function can be used to reconstruct GRNs based on pre-existing GRNs saved in Links object.

Parameters **links_object** ([Links](#)) – Please see the explanation of Links class.

get_links (*cluster_name_for_GRN_unit=None*, *alpha=10*, *bagging_number=20*, *verbose_level=1*, *test_mode=False*)

Makes GRN for each cluster and returns results as a Links object. Several preprocessing should be done before using this function.

Parameters

- **cluster_name_for_GRN_unit** (*str*) – Cluster name for GRN calculation. The cluster information should be stored in Oracle.adata.obs.

- **alpha** (*float or int*) – The strength of regularization. If you set a lower value, the sensitivity increases, and you can detect weaker network connections. However, there may be more noise. If you select a higher value, it will reduce the chance of overfitting.
- **bagging_number** (*int*) – The number used in bagging calculation.
- **verbose_level** (*int*) – if [verbose_level>1], most detailed progress information will be shown. if [verbose_level > 0], one progress bar will be shown. if [verbose_level == 0], no progress bar will be shown.
- **test_mode** (*bool*) – If test_mode is True, GRN calculation will be done for only one cluster rather than all clusters.

get_mcmc_cell_transition_table (*cluster_column_name=None, end=-1*)

Return cell count in the initial state and final state after mcmc. Cell counts are grouped by the cluster of interest. Result will be returned as 2D matrix.

import_TF_data (*TF_info_matrix=None, TF_info_matrix_path=None, TFdict=None*)

Load data about potential-regulatory TFs. You can import either TF_info_matrix or TFdict. For more information on how to make these files, please see the motif analysis module within the celloracle tutorial.

Parameters

- **TF_info_matrix** (*pandas.DataFrame*) – TF_info_matrix.
- **TF_info_matrix_path** (*str*) – File path for TF_info_matrix (*pandas.DataFrame*).
- **TFdict** (*dictionary*) – Python dictionary of TF info.

import_anndata_as_normalized_count (*adata, cluster_column_name=None, embedding_name=None, test_mode=False*)

Load scRNA-seq data. scRNA-seq data should be prepared as an anndata object. Preprocessing (cell and gene filtering, dimensional reduction, clustering, etc.) should be done before loading data. The method will import NORMALIZED and LOG TRANSFORMED data but NOT SCALED and NOT CENTERED data. See the tutorial for more details on how to process scRNA-seq data.

Parameters

- **adata** (*anndata*) – anndata object containing scRNA-seq data.
- **cluster_column_name** (*str*) – the name of column containing cluster information in anndata.obs. Clustering data should be in anndata.obs.
- **embedding_name** (*str*) – the key name for dimensional reduction information in anndata.obsm. Dimensional reduction (or 2D trajectory graph) should be in anndata.obsm.
- **transform** (*str*) – The method for log-transformation. Chose one from “natural_log” or “log2”.

import_anndata_as_raw_count (*adata, cluster_column_name=None, embedding_name=None, transform='natural_log'*)

Load scRNA-seq data. scRNA-seq data should be prepared as an anndata object. Preprocessing (cell and gene filtering, dimensional reduction, clustering, etc.) should be done before loading data. The method imports RAW GENE COUNTS because unscaled and uncentered gene expression data are required for the GRN inference and simulation. See tutorial notebook for the details about how to process scRNA-seq data.

Parameters

- **adata** (*anndata*) – anndata object that stores scRNA-seq data.
- **cluster_column_name** (*str*) – the name of column containing cluster information in anndata.obs. Clustering data should be in anndata.obs.

- **embedding_name** (*str*) – the key name for dimensional reduction information in anndata.obsm. Dimensional reduction (or 2D trajectory graph) should be in anndata.obsm.
- **transform** (*str*) – The method for log-transformation. Chose one from “natural_log” or “log2”.

plot_mc_result_as_kde (*n_time*, *args={}*)

Pick up one timepoint in the cell state-transition simulation and plot as a kde plot.

Parameters

- **n_time** (*int*) – the number in Markov simulation
- **args** (*dictionary*) – An argument for seaborn.kdeplot. See seaborn documentation for details (<https://seaborn.pydata.org/generated/seaborn.kdeplot.html#seaborn.kdeplot>).

plot_mc_result_as_trajectory (*cell_name*, *time_range*, *args={}*)

Pick up several timepoints in the cell state-transition simulation and plot as a line plot. This function can be used to visualize how cell-state changes after perturbation focusing on a specific cell.

Parameters

- **cell_name** (*str*) – cell name. chose from adata.obs.index
- **time_range** (*list of int*) – the list of index in Markov simulation
- **args** (*dictionary*) – dictionary for the arguments for matplotlib.pyplot.plot. See matplotlib documentation for details (https://matplotlib.org/api/_as_gen/matplotlib.pyplot.plot.html#matplotlib.pyplot.plot).

plot_mc_results_as_sankey (*cluster_use*, *start=0*, *end=-1*, *order=None*, *font_size=10*)

Plot the simulated cell state-transition as a Sankey-diagram after groping by the cluster.

Parameters

- **cluster_use** (*str*) – cluster information name in anndata.obs. You can use any cluster information in anndata.obs.
- **start** (*int*) – The starting point of Sankey-diagram. Please select a step in the Markov simulation.
- **end** (*int*) – The end point of Sankey-diagram. Please select a step in the Markov simulation. if you set [end=-1], the final step of Markov simulation will be used.
- **order** (*list of str*) – The order of cluster name in the Sankey-diagram.
- **font_size** (*int*) – Font size for cluster name label in the Sankey diagram.

prepare_markov_simulation (*verbose=False*)

Pick up cells for Markov simulation.

Parameters **verbose** (*bool*) – If True, it plots selected cells.

run_markov_chain_simulation (*n_steps=500*, *n_duplication=5*, *seed=123*, *calculation_randomized=True*)

Do Markov simulations to predict cell transition after perturbation. The transition probability between cells has been calculated based on simulated gene expression values in the signal propagation process. The cell state transition will be simulated based on the probability. You can simulate the process multiple times to get a robust outcome.

Parameters

- **n_steps** (*int*) – steps for Markov simulation. This value is equivalent to the amount of time after perturbation.
- **n_duplication** (*int*) – the number for multiple calculations.

simulate_shift (*perturb_condition=None*, *GRN_unit=None*, *n_propagation=3*, *ignore_warning=False*)

Simulate signal propagation with GRNs. Please see the CellOracle paper for details. This function simulates a gene expression pattern in the near future. Simulated values will be stored in anndata.layers: [“simulated_count”]

The simulation use three types of data. (1) GRN inference results (coef_matrix). (2) Perturb_condition: You can set arbitrary perturbation condition. (3) Gene expression matrix: The simulation starts from imputed gene expression data.

Parameters

- **perturb_condition** (*dictionary*) – condition for perturbation. if you want to simulate knockout for GeneX, please set [perturb_condition={“GeneX”: 0.0}] Although you can set any non-negative values for the gene condition, avoid setting biologically infeasible values for the perturb condition. It is strongly recommended to check gene expression values in your data before selecting the perturb condition.
- **GRN_unit** (*str*) – GRN type. Please select either “whole” or “cluster”. See the documentation of “fit_GRN_for_simulation” for the detailed explanation.
- **n_propagation** (*int*) – Calculation will be performed iteratively to simulate signal propagation in GRN. You can set the number of steps for this calculation. With a higher number, the results may recapitulate signal propagation for many genes. However, a higher number of propagation may cause more error/noise.

suggest_mass_thresholds (*n_suggestion=12*, *s=1*, *n_col=4*)

summarize_mc_results_by_cluster (*cluster_use*, *random=False*)

This function summarizes the simulated cell state-transition by groping the results into each cluster. It returns summarized results as a pandas.DataFrame.

Parameters **cluster_use** (*str*) – cluster information name in anndata.obs. You can use any arbitrary cluster information in anndata.obs.

to_hdf5 (*file_path*)

Save object as hdf5.

Parameters **file_path** (*str*) – file path to save file. Filename needs to end with ‘.celloracle.oracle’

updateTFinfo_dictionary (*TFdict={}*)

Update a TF dictionary. If a key in the new TF dictionary already exists in the old TF dictionary, old values will be replaced with a new one.

Parameters **TFdict** (*dictionary*) – Python dictionary of TF info.

celloracle.check_python_requirements (*return_detail=True*, *print_warning=True*)

Check installation status and requirements of dependant libraries.

celloracle.load_hdf5 (*file_path*, *object_class_name=None*)

Load an object of celloracle’s custom class that was saved as hdf5.

Parameters

- **file_path** (*str*) – file_path.
- **object_class_name** (*str*) – Types of object. If it is None, object class will be identified from the extension of file_name. Default is None.

celloracle.test_R_libraries_installation (*show_all_stdout=False*)

CellOracle.network_analysis use several R libraries for network analysis. This is a test function to check for instalation of the necessary R libraries.

Modules for ATAC-seq analysis

celloracle.motif_analysis module

The `motif_analysis` module implements transcription factor motif scan.

Genomic activity information (peak of ATAC-seq or Chip-seq) is extracted first. Then the peak DNA sequence will be subjected to TF motif scan. Finally we will get list of TFs that potentially binds to a specific gene.

```
class celloracle.motif_analysis.TFinfo(peak_data_frame, ref_genome)
    Bases: object
```

This is a custom class for motif analysis in celloracle. TFinfo object performs motif scan using the TF motif database in gimmemotifs and several functions of genomepy. Analysis results can be exported as a python dictionary or dataframe. These files; python dictionary of dataframe of TF binding information, are needed during GRN inference.

peak_df

dataframe about DNA peak and target gene data.

Type pandas.DataFrame

all_target_gene

target genes.

Type array of str

ref_genome

reference genome name that was used in DNA peak generation.

Type str

scanned_df

Results of motif scan. Key is a peak name. Value is a dataframe of motif scan.

Type dictionary

dic_targetgene2TFs

Final product of motif scan. Key is a target gene. Value is a list of regulatory candidate genes.

Type dictionary

dic_peak2Targetgene

Dictionary. Key is a peak name. Value is a list of the target gene.

Type dictionary

dic_TF2targetgenes

Final product of motif scan. Key is a TF. Value is a list of potential target genes of the TF.

Type dictionary

copy()

Deepcopy itself.

filter_motifs_by_score(threshold, method='cumulative_score')

Remove motifs with low binding scores.

Parameters **method** (str) – thresholding method. Select either of [“individual_score”, “cumulative_score”]

filter_peaks(peaks_to_be_remainded)

Filter peaks.

Parameters **peaks_to_be_remainded** (array of str) – list of peaks. Peaks that are NOT in the list will be removed.

`make_TFinfo_dataframe_and_dictionary`(*verbose=True*)

This is the final step of motif_analysis. Convert scanned results into a data frame and dictionaries.

Parameters `verbose` (*bool*) – Whether to show a progress bar.

`reset_dictionary_and_df()`

Reset TF dictionary and TF dataframe. The following attributes will be erased: TF_onehot, dic_targetgene2TFs, dic_peak2Targetgene, dic_TF2targetgenes.

`reset_filtering()`

Reset filtering information. You can use this function to start over the filtering step with new conditions. The following attributes will be erased: TF_onehot, dic_targetgene2TFs, dic_peak2Targetgene, dic_TF2targetgenes.

`save_as_parquet`(*folder_path=None*)

Save itself. Some attributes are saved as parquet file.

Parameters `folder_path` (*str*) – folder path

`scan`(*background_length=200, fpr=0.02, n_cpus=-1, verbose=True, motifs=None, TF_evidence_level='direct_and_indirect', TF_formatting='auto'*)

Scan DNA sequences searching for TF binding motifs.

Parameters

- `background_length` (*int*) – background length. This is used for the calculation of the binding score.
- `fpr` (*float*) – False positive rate for motif identification.
- `n_cpus` (*int*) – number of CPUs for parallel calculation.
- `verbose` (*bool*) – Whether to show a progress bar.
- `motifs` (*list*) – a list of gimmemotifs motifs, will revert to default_motifs() if None
- `TF_evidence_level` (*str*) – Please select one from [“direct”, “direct_and_indirect”]. If “direct” is selected, TFs that have a binding evidence were used. If “direct_and_indirect” is selected, TFs with binding evidence and inferred TFs are used. For more information, please read explanation of Motif class in gimmemotifs documentation (<https://gimmemotifs.readthedocs.io/en/master/index.html>)

`to_dataframe`(*verbose=True*)

Return results as a dataframe. Rows are peak_id, and columns are TFs.

Parameters `verbose` (*bool*) – Whether to show a progress bar.

Returns TFinfo matrix.

Return type pandas.dataframe

`to_dictionary`(*dictionary_type='targetgene2TFs', verbose=True*)

Return TF information as a python dictionary.

Parameters `dictionary_type` (*str*) – Type of dictionary. Select from [“targetgene2TFs”, “TF2targetgenes”]. If you chose “targetgene2TFs”, it returns a dictionary in which a key is a target gene, and a value is a list of regulatory candidate genes (TFs) of the target. If you chose “TF2targetgenes”, it returns a dictionary in which a key is a TF and a value is a list of potential target genes of the TF.

Returns dictionary.

Return type dictionary

`to_hdf5`(*file_path*)

Save object as hdf5.

Parameters `file_path` (*str*) – file path to save file. Filename needs to end with ‘.celloracle.tfinfo’

```
celloracle.motif_analysis.get_tss_info(peak_str_list,      ref_genome,      ver-
                                         bose=True)
Get annotation about Transcription Starting Site (TSS).
```

Parameters

- **peak_str_list** (*list of str*) – list of peak_id. e.g.,
[“chr5_0930303_9499409”, “chr11_123445555_123445577”]
- **ref_genome** (*str*) – reference genome name.
- **verbose** (*bool*) – verbosity.

```
celloracle.motif_analysis.integrate_tss_peak_with_cicero(tss_peak,      ci-
                                                               cero_connections)
```

Process output of cicero data and returns DNA peak information for motif analysis in celloracle.
Please see the celloracle tutorial for more information.

Parameters

- **tss_peak** (*pandas.DataFrame*) – dataframe about TSS information. Please use the function, “get_tss_info” to get this dataframe.
- **cicero_connections** (*Dataframe*) – dataframe that stores the results of cicero analysis.

Returns DNA peak about promoter/enhancer and its annotation about target gene.

Return type *pandas.DataFrame*

```
celloracle.motif_analysis.is_genome_installed(ref_genome)
```

Celloracle motif_analysis module uses gimmemotifs and genomepy internally. Reference genome files should be installed in the PC to use gimmemotifs and genomepy. This function checks the installation status of the reference genome.

Parameters **ref_genome** (*str*) – names of reference genome. i.e., “mm10”, “hg19”

```
celloracle.motif_analysis.load_TFinfo(file_path)
```

Load TFinfo object which was saved as hdf5 file.

Parameters **file_path** (*str*) – file path.

Returns Loaded TFinfo object.

Return type *TFinfo*

```
celloracle.motif_analysis.load_TFinfo_from_parquets(folder_path)
```

Load TFinfo object which was saved with the function; “save_as_parquet”.

Parameters **folder_path** (*str*) – folder path

Returns Loaded TFinfo object.

Return type *TFinfo*

```
celloracle.motif_analysis.load_motifs(motifs_name)
```

Load motifs from celloracle motif database

Parameters **motifs_name** (*str*) – Name of motifs.

Returns List of gimmemotifs.motif object.

Return type list

```
celloracle.motif_analysis.make_TFinfo_from_scanned_file(path_to_raw_bed,
                                                       path_to_scanned_result_bed,
                                                       ref_genome)
```

This function is currently an available.

```
celloracle.motif_analysis.peak2fasta(peak_ids, ref_genome)
Convert peak_id into fasta object.
```

Parameters

- **peak_id** (*str or list of str*) – Peak_id. e.g. “chr5_0930303_9499409” or it can be a list of peak_id. e.g. [“chr5_0930303_9499409”, “chr11_123445555_123445577”]
- **ref_genome** (*str*) – Reference genome name. e.g. “mm9”, “mm10”, “hg19” etc

Returns DNA sequence in fasta format

Return type gimmemotifs.fasta object

```
celloracle.motif_analysis.read_bed(bed_path)
```

Load bed file and return as dataframe.

Parameters **bed_path** (*str*) – File path.

Returns bed file in dataframe.

Return type pandas.dataframe

```
celloracle.motif_analysis.remove_zero_seq(fasta_object)
```

Remove DNA sequence with zero length

```
celloracle.motif_analysis.scan_dna_for_motifs(scanner_object,          motifs_object, sequence_object, verbose=True)
```

This is a wrapper function to scan DNA sequences searchig for Gene motifs.

Parameters

- **scanner_object** (*gimmemotifs.scanner*) – Object that do motif scan.
- **motifs_object** (*gimmemotifs.motifs*) – Object that stores motif data.
- **sequence_object** (*gimmemotifs.fasta*) – Object that stores sequence data.

Returns scan results is stored in data frame.

Return type pandas.dataframe

Modules for Network analysis

celloracle.network_analysis module

The *network_analysis* module implements Network analysis.

```
class celloracle.network_analysis.Links(name, links_dict={})
Bases: object
```

This is a class for the processing and visualization of GRNs. Links object stores cluster-specific GRNs and metadata. Please use “get_links” function in Oracle object to generate Links object.

links_dict

Dictionary that store unprocessed network data.

Type dictionary

filtered_links

Dictionary that store filtered network data.

Type dictionary

merged_score

Network scores.

Type pandas.dataframe

cluster

List of cluster name.

Type list of str

name

Name of clustering unit.

Type str

palette

DataFrame that store color information.

Type pandas.dataframe

filter_links (*p=0.001, weight='coef_abs', thread_number=10000, genelist_source=None, genelist_target=None*)

Filter network edges. In most cases, inferred GRN has non-significant random edges. We have to remove these edges before analyzing the network structure. You can do the filtering in any of the following ways.

- (1) Filter based on the p-value of the network edge. Please enter p-value for thresholding.
- (2) Filter based on network edge number. If you set the number, network edges will be filtered based on the order of a network score. The top n-th network edges with network weight will remain, and the other edges will be removed. The network data has several types of network weight, so you have to select which network weight do you want to use.
- (3) Filter based on an arbitrary gene list. You can set a gene list for source nodes or target nodes.

Parameters

- **p** (*float*) – threshold for p-value of the network edge.
- **weight** (*str*) – Please select network weight name for the filtering
- **genelist_source** (*list of str*) – gene list to remain in regulatory gene nodes. Default is None.
- **genelist_target** (*list of str*) – gene list to remain in target gene nodes. Default is None.

get_network_entropy (*value='coef_abs'*)

Calculate network entropy scores.

Parameters **value** (*str*) – Default is “coef_abs”.

get_score (*test_mode=False*)

Get several network scores using R libraries. Make sure all dependent R libraries are installed in your environment before running this function. You can check the installation for the R libraries by running test_installation() in network_analysis module.

```
plot_cartography_scatter_per_cluster(gois=None, clusters=None,
                                         scatter=True, kde=False,
                                         auto_gene_annot=False, per-
                                         centile=98, args_dot={'n_levels':
                                         105}, args_line={'c': 'gray'},
                                         args_annot={}, save=None)
```

Make a gene network cartography plot. Please read the original paper describing gene network cartography for more information. <https://www.nature.com/articles/nature03288>

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **gois** (*list of str*) – List of gene name to highlight.
- **clusters** (*list of str*) – List of cluster name to analyze. If None, all clusters in `Links` object will be analyzed.
- **scatter** (*bool*) – Whether to make a scatter plot.
- **auto_gene_annot** (*bool*) – Whether to pick up genes to make an annotation.
- **percentile** (*float*) – Genes with a network score above the percentile will be shown with annotation. Default is 98.
- **args_dot** (*dictionary*) – Arguments for scatter plot.
- **args_line** (*dictionary*) – Arguments for lines in cartography plot.
- **args_annot** (*dictionary*) – Arguments for annotation in plots.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

```
plot_cartography_term(goi, save=None, plt_show=True)
```

Plot the gene network cartography term like a heatmap. Please read the original paper of gene network cartography for the principle of gene network cartography. <https://www.nature.com/articles/nature03288>

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **gois** (*list of str*) – List of gene name to highlight.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

```
plot_degree_distributions(plot_model=False, save=None)
```

Plot the network degree distributions (the number of edge per gene). The network degree will be visualized in both linear scale and log scale.

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **plot_model** (*bool*) – Whether to plot linear approximation line.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

```
plot_network_entropy_distributions(update_network_entropy=False,
                                         save=None)
```

Plot the distribution for network entropy. See the CellOracle paper for more detail.

Parameters

- **links** (*Links object*) – See `network_analysis.Links` class for detail.
- **values** (*list of str*) – The list of score to visualize. If it is None, all network score (listed above) will be used.
- **update_network_entropy** (*bool*) – Whether to recalculate network entropy.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is

None.

```
plot_score_comparison_2D(value, cluster1, cluster2, percentile=99, annot_shifts=None, save=None, plt_show=True, interactive=False)
```

Make a scatter plot that compares specific network scores in two groups.

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **value** (*srt*) – The network score type.
- **cluster1** (*str*) – Cluster name. Network scores in cluster1 will be visualized in the x-axis.
- **cluster2** (*str*) – Cluster name. Network scores in cluster2 will be visualized in the y-axis.
- **percentile** (*float*) – Genes with a network score above the percentile will be shown with annotation. Default is 99.
- **annot_shifts** ((*float*, *float*)) – Annotation visualization setting.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

```
plot_score_distributions(values=None, method='boxplot', save=None)
```

Plot the distribution of network scores. An individual data point is a network edge (gene).

Parameters

- **links** ([Links](#)) – See `Links` class for details.
- **values** (*list of str*) – The list of score to visualize. If it is None, all of the network score will be used.
- **method** (*str*) – Plotting method. Select either “boxplot” or “barplot”.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

```
plot_score_per_cluster(goi, save=None, plt_show=True)
```

Plot network score for a gene. This function visualizes the network score for a specific gene between clusters to get an insight into the dynamics of the gene.

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **goi** (*srt*) – Gene name.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

```
plot_scores_as_rank(cluster, n_gene=50, save=None)
```

Pick up top n-th genes with high-network scores and make plots.

Parameters

- **links** ([Links](#)) – See `network_analysis.Links` class for detail.
- **cluster** (*str*) – Cluster name to analyze.
- **n_gene** (*int*) – Number of genes to plot. Default is 50.
- **save** (*str*) – Folder path to save plots. If the folder does not exist in the path, the function creates the folder. Plots will not be saved if [save=None]. Default is None.

```
to_hdf5(file_path)
```

Save object as hdf5.

Parameters **file_path** (*str*) – file path to save file. Filename needs to end with ‘.celloracle.links’

```
celloracle.network_analysis.draw_network(linkList, return_graph=False)
```

Plot network graph.

Parameters

- **linkList** (*pandas.DataFrame*) – GRN saved as linkList.
- **return_graph** (*bool*) – Whether to return graph object.

Returns Network X graph objenct.

Return type Graph object

```
celloracle.network_analysis.get_R_path()
celloracle.network_analysis.get_links(oracle_object,
                                      cluster_name_for_GRN_unit=None,
                                      alpha=10, bagging_number=20,
                                      verbose_level=1, test_mode=False)
```

Make GRN for each cluster and returns results as a Links object. Several preprocessing should be done before using this function.

Parameters

- **oracle_object** (*Oracle*) – See Oracle module for detail.
- **cluster_name_for_GRN_unit** (*str*) – Cluster name for GRN calculation. The cluster information should be stored in Oracle.adata.obs.
- **alpha** (*float or int*) – The strength of regularization. If you set a lower value, the sensitivity increases, and you can detect weaker network connections. However, there may be more noise. If you select a higher value, it will reduce the chance of overfitting.
- **bagging_number** (*int*) – The number used in bagging calculation.
- **verbose_level** (*int*) – if [verbose_level>1], most detailed progress information will be shown. if [verbose_level > 0], one progress bar will be shown. if [verbose_level == 0], no progress bar will be shown.
- **test_mode** (*bool*) – If test_mode is True, GRN calculation will be done for only one cluster rather than all clusters.

```
celloracle.network_analysis.linkList_to_networkgraph(filteredlinkList)
Convert linkList into Graph object in NetworkX.
```

Parameters **filteredlinkList** (*pandas.DataFrame*) – GRN saved as linkList.

Returns Network X graph objenct.

Return type Graph object

```
celloracle.network_analysis.load_links(file_path)
Load links object saved as a hdf5 file.
```

Parameters **file_path** (*str*) – file path.

Returns loaded links object.

Return type *Links*

```
celloracle.network_analysis.set_R_path(R_path)
```

```
celloracle.network_analysis.test_R_libraries_installation(show_all_stdout=False)
CellOracle.network_analysis use several R libraries for network analysis. This is a test function to
check for instalation of the necessary R libraries.
```

```
celloracle.network_analysis.transfer_scores_from_links_to_adata(adata,  
                                                               links,  
                                                               method='median')
```

Transfer the summary of network scores (median or mean) per group from Links object into adata.

Parameters

- **adata** (*anndata*) – anndata
- **links** ([Links](#)) – Likns object
- **method** (*str*) – The method to summarize data.

Other modules

[celloracle.go_analysis module](#)

The [go_analysis](#) module implements Gene Ontology analysis. This module use goatools internally.

```
celloracle.go_analysis.geneID2Symbol (IDs, species='mouse')
```

Convert Entrez gene id into gene symbol.

Parameters

- **IDs** (*array of str*) – Entrez gene id.
- **species** (*str*) – Select species. Either “mouse” or “human”.

Returns Gene symbol

Return type list of str

```
celloracle.go_analysis.geneSymbol2ID (symbols, species='mouse')
```

Convert gene symbol into Entrez gene id.

Parameters

- **symbols** (*array of str*) – gene symbol
- **species** (*str*) – Select species. Either “mouse” or “human”

Returns Entrez gene id

Return type list of str

```
celloracle.go_analysis.get_GO (gene_query, species='mouse')
```

Get Gene Ontologies (GOs).

Parameters

- **gene_query** (*array of str*) – gene list.
- **species** (*str*) – Select species. Either “mouse” or “human”

Returns GO analysis results as dataframe.

Return type pandas.dataframe

[celloracle.utility module](#)

The [utility](#) module has several functions that support celloracle.

```
celloracle.utility.exec_process (commands, message=True,  
                                 wait_finished=True, re-  
                                 turn_process=True)
```

Excute a command. This is a wrapper of “subprocess.Popen”

Parameters

- **commands** (*str*) – command.
- **message** (*bool*) – Whether to return a message or not.

- **wait_finished (bool)** – Whether or not to wait for the process to finish. If false, the process will be performed in background and the function will finish immediately
- **return_process (bool)** – Whether to return “process”.

`celloracle.utility.intersect (list1, list2)`

Intersect two list and get components that exists in both list.

Parameters

- **list1 (list)** – input list.
- **list2 (list)** – input list.

Returns intersected list.

Return type list

```
celloracle.utility.knn_data_transferer (adata_ref, adata_que,
                                       n_neighbors=20, cluster_name=None,
                                       embedding_name=None, adata_true=None,
                                       transfer_color=True, n_PCA=30,
                                       use_PCA_in_adata=False)
```

Extract categorical information from adata.obs or embedding information from adata.obsm and transfer these information into query anndata. In the calculation, KNN is used after PCA.

Parameters

- **adata_ref (anndata)** – reference anndata
- **adata_que (anndata)** – query anndata
- **cluster_name (str or list of str)** – cluster name(s) to be transferred. If you want to transfer multiple data, you can set the cluster names as a list.
- **embedding_name (str or list of str)** – embedding name(s) to be transferred. If you want to transfer multiple data, you can set the embedding names as a list.
- **adata_true (str)** – This argument can be used for the validation of this algorithm. If you have true answer, you can set it. If you set true answer, the function will return some metrics for benchmarking.
- **transfer_color (bool)** – Whether or not to transfer color data in addition to cluster information.
- **n_PCA (int)** – Number of PCs that will be used for the input of KNN algorithm.

`celloracle.utility.load_hdf5 (file_path, object_class_name=None)`

Load an object of celloracle’s custom class that was saved as hdf5.

Parameters

- **file_path (str)** – file_path.
- **object_class_name (str)** – Types of object. If it is None, object class will be identified from the extension of file_name. Default is None.

`celloracle.utility.load_pickled_object (filepath)`

Load pickled object.

Parameters `filepath (str)` – file path.

Returns loaded object.

Return type python object

class `celloracle.utility.makelog (file_name=None, directory=None)`

Bases: object

This is a class for making log.

info (*comment*)

Add comment into the log file.

Parameters **comment** (*str*) – comment.

celloracle.utility.save_as_pickled_object (*obj, filepath*)

Save any object using pickle.

Parameters

- **obj** (*any python object*) – python object.
- **filepath** (*str*) – file path.

celloracle.utility.standard (*df*)

Standardize value.

Parameters **df** (*pandas.DataFrame*) – dataframe.

Returns Data after standardization.

Return type pandas.DataFrame

celloracle.utility.transfer_all_colors_between_anndata (*adata_ref, adata_que*)

Extract all color information from reference anndata and transfer the color into query anndata.

Parameters

- **adata_ref** (*anndata*) – reference anndata
- **adata_que** (*anndata*) – query anndata

celloracle.utility.transfer_color_between_anndata (*adata_ref, adata_que, clus- ter_name*)

Extract color information from reference anndata and transfer the color into query anndata.

Parameters

- **adata_ref** (*anndata*) – reference anndata
- **adata_que** (*anndata*) – query anndata
- **cluster_name** (*str*) – cluster name. This information should exist in the anndata.obs.

celloracle.utility.update_adata (*adata*)

celloracle.data module

The `data` module implements data download and loading.

celloracle.data.load_Paul2015_data()

Load mouse hematopoiesis scRNA-seq data. The data was processed according to the standard CellOracle preprocessing method described in the tutorial.

celloracle.data.load_TFinfo_df_mm9_mouse_atac_atlas()

Load Transcription factor binding information made from mouse scATAC-seq atlas dataset. mm9 genome was used for the reference genome.

Args:

Returns TF binding info.

Return type pandas.DataFrame

celloracle.data.load_tutorial_links_object()**celloracle.data.load_tutorial_oracle_object()**

celloracle.data_conversion module

The `data_conversion` module implements data conversion between different platform.

```
celloracle.data_conversion.seurat_object_to_anndata(file_path_seurat_object,
                                                    delete_tmp_file=True)
```

Convert seurat object into anndata.

Parameters

- `file_path_seurat_object (str)` – File path of seurat object. Seurat object should be saved as Rds format.
- `delete_tmp_file (bool)` – Whether to delete temporary file.

Returns anndata object.

Return type anndata

1.5 Changelog

• 0.5.1 <2020-08-4>

- Add new promoter-TSS reference data for several reference genomes; (1)"Xenopus": ["xenTro2", "xenTro3"], (2)"Rat": ["rn4", "rn5", "rn6"], (3)"Drosophila": ["dm3", "dm6"], (4)"C.elegans": ["ce6", "ce10"], (5)"Arabidopsis": ["tair10"]].

- Add new motif data for several species: "Xenopus", "Rat", "Drosophila", "C.elegans" and "Arabidopsis".

• 0.5.0 <2020-08-3>

- Add new functions for custom motifs. You can select motifs from several options. Also, we updated our web tutorial to introduce how to load / make a different motif data.

- Change default motifs for S.cerevisiae and Zebrafish.

- Change requirements for dependent package: gimmemotifs and geomepy. Celloracle codes were updated to support new version of gimmemotifs (0.14.4) and geomepy (0.8.4).

• 0.4.2 <2020-07-14>

- Add promoter-TSS information for Zebrafish reference genome (danRer7, danRer10 and danRer11).

• 0.4.1 <2020-07-02>

- Add promoter-TSS information for S.cerevisiae reference genome (sacCer2 and sacCer3).

• 0.4.0 <2020-06-28>

- Change requirements.

- From this version, pandas version 1.0.3 or later is required.

- From this version, scanpy version 1.5.3 or later is required.

• 0.3.7 <2020-06-12>

- Delete GO function from r-script

- Update some functions for network visualization

• 0.3.6 <2020-06-08>

- Fix a bug on the transition probability calculation in Markov simulation

- Add new function "count_cells_in_mc_results" to oracle class

- 0.3.5 <2020-05-09>
 - Fix a bug on the function for gene cortography visualization
 - Change some settings for installation
 - Update data conversion module
- 0.3.4 <2020-04-29>
 - Change pandas version restriction
 - Fix a bug on the function for gene cortography visualization
 - Add new functions for R-path configuration
- 0.3.3 <2020-04-24>
 - Add promoter-TSS information for hg19 and hg38 reference genome
- 0.3.1 <2020-03-23>
 - Fix an error when try to save file larger than 4GB file
- 0.3.0 <2020-2-17>
 - Release beta version

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

“License” shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

“Licensor” shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

“Legal Entity” shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, “control” means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

“You” (or “Your”) shall mean an individual or Legal Entity exercising permissions granted by this License.

“Source” form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

“Object” form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

“Work” shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

“Derivative Works” shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an

original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

“Contribution” shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, “submitted” means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as “Not a Contribution.”

“Contributor” shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

- (a) You must give any other recipients of the Work or Derivative Works a copy of this License; and
- (b) You must cause any modified files to carry prominent notices stating that You changed the files; and
- (c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
- (d) If the Work includes a “NOTICE” text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an “AS IS” BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets “[]” replaced with your own identifying information. (Don’t include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same “printed page” as the copyright notice for easier identification within third-party archives.
